Package: AlgebraicHaploPackage (via r-universe)

September 1, 2024

Type Package

Title Haplotype Two Snips Out of a Paired Group of Patients

Version 1.2

Date 2015-10-26

Author Jan Wolfertz

Maintainer Jan Wolfertz <Jan.wolfertz@uni-duesseldorf.de>

Depends R (>= 3.1.3)

Suggests compiler

Description Two unordered pairs of data of two different snips positions is haplotyped by resolving a small number ob closed equations.

LazyLoad yes

License GPL-2

AlgebraicHaploPackage-package

AlgebraicHaploPackage— The package haplotype a contingency of two pairs of snips of a sample.

Description

Assume a group of patients of an unordered pair of data per snips. The contingency table of 2 snips on diffrent positions are calculated. A haplotype 2x2 most likely contingency table is guessed.

Details

Package:	AlgebraicHaploPackage
Type:	Package
Version:	1.2
Date:	2015-10-26
License:	GPL2.0

Examples

```
print("The second example: \n")
dd=matrix(c(1212, 2, 0, 679, 0,0,75,0,0), byrow=TRUE, nrow=3)
colnames(dd)=c("CC","CT","TT")
rownames(dd)=c("CC","CT","TT")
callhaplotype(dd)
### Check the result of the cubic equation of the second example
print("##############################")
print("Check the result of the cubic equation of the second example: \n")
```

```
temp2haplo =as.numeric(t(dd));
t2h=temp2haplo
haplotypeit(t2h[1],t2h[2],t2h[3],t2h[4],t2h[5],t2h[6],t2h[7],t2h[8],t2h[9]);
rm(temp2haplo)
rm(t2h)
### Third example
print("##############################")
print("Third example : \n")
dd3=matrix(c(1030,678,123,1,1,0,0,0,0),ncol=3,byrow=TRUE)
colnames(dd3)=c("AA","AG","GG")
rownames(dd3)=c("CC","CT","TT")
callhaplotype(dd3)
###  Check for alternative solutions
print("##############################")
print("Check for alternative solutions: \n")
temp2haplo =as.numeric(t(dd3));
t2h=temp2haplo;
haplotypeit(t2h[1],t2h[2],t2h[3],t2h[4],t2h[5],t2h[6],t2h[7],t2h[8],t2h[9]);
rm(temp2haplo)
rm(t2h)
print("##############################")
print("##############################")
print("This tests the result of the first example of the article \n")
dd2=matrix(c(4,0,0,0,30,0,0,0,23),ncol=3,byrow=TRUE)
callhaplotype(dd2)
callhaplotype(dd2)/(2*57)
print("##############################")
```

`callhaplotype` *calcultes the cotigency table of the haplotypes*

Description

It starts with a contigency table of pairs of haplotypes and ends up with the haplotypes one. The heterocygote cases are the middle of the column and rows.

Usage

```
callhaplotype(dd)
```

Arguments

dd	This is a contingency table. Rows and columns are in the order are AA, AB,BB.

Details

A 2x2 contingency table of haplotypes is calculated. The most likely solution had been choosen.

Value

The haplotype contingency table is returned. All entries are numeric.

Note

The differences are the coice of the solution of the cubic equations. About 4 percent differences and about 7 assuming 1 per thousand. For data export or import you can use a different package.

`cubic` *Function that can resolve the cubic equation numerical stable and any lower dimensional case except unsolvable cases.*

Description

A*x^3+B*x^2+C*x+D=0. All coefficients had to be numeric or integers. This function calculates from 4 coefficient all possible and senfully solutions. D=0 returns no values at all. This would be a impossibel case. It returns upto 3 potential complex solutions. Less solutions are copied to get the tripple solution format.

Usage

```
cubic(A, B, C, D)
```

Arguments

A	The coefficient of x^3.
B	The coefficient of x^2.
C	The coefficient of X.
D	The constant.

Details

This function is called by haplotypeit. The results are returned as vector of the three possible solutions: output[1],output[2],output[3]. Further data for checks of the roots. p,q and the discriminat. 10 and 11 are only usable for symmetry checks.

Value

Returns `cubic(A,B,C,D)[c(1:3)]` roots of the at most cubic equation.

Note

Using cardenian formular, a well known method.

Author(s)

Jan Wolfertz

cubic(1,1,0,0)[c(1:3)]
```

`findoptimal` *Chose the most likely solution of the three potential onces.*

Description

Starting with a 3x3 matrix, three potential haplotypes 2x2 matrices will be calculted and evaluated. The most likly one is choosen. A dicrete solution values are not enforced. This reduces increases the right prediction on real data.

Usage

```
findoptimal(A, B, C, D, mmorg, exact = 1e-05)
```

Arguments

`A`	Firts entry of the 2x2 matrix.
`B`	Second numeric entry of teh 2x2 matrix.
`C`	Third numeric entry of the 2x2 matrix.
`D`	Last numeric entry of the 2x2 matrix.
`mmorg`	3x3 matrix of the pair of original snip pairs.
`exact`	`exact` is a parameter when data are assumed to be equal. Acutually 1e-5 is taken. Should not be larger than the invers of four times the number of people.

Details

It chose the 2x2 model of haplotypes with the smallest prediction error.

Value

`AA`	Coefficient of x^3
`BB`	Coefficient of x^2
`CC`	Coefficient of x
`DD`	Coefficient of the intercept

Author(s)

Jan wolfertz

Examples

```
dd2=matrix(c(4,0,0,0,30,0,0,0,23),ncol=3,byrow=TRUE)
A=c(38+0i,2+12.1655i,2-12.1655i)
B=c(0+0i,36-12.1655i,36+12.1655i)
C=c(0+0i,36-12.1655i,36+12.1655i)
D=c(76+0i,40+12.1655i,40-12.1655i)
```

`haplotypeit` *Haplotype a 3 x 3 counting matrix.*

Description

This functions recalculates the potential 2x2 haplotype matrics. It gets a 3x3 matrixs and returns a list A,B,C,D of vectors. A[1],B[1],C[1],D[1] is the first solution of the matrix. There are always three solutions.

Usage

```
haplotypeit(a, b, c, d, e, f, g, h, i)
```

Arguments

a	Number of counts of matching snip pairs.
b	Number of counts of matching snip pairs..
c	Number of counts of matching snip pairs.
d	Number of counts of matching snip pairs.
e	Number of counts of matching snip pairs.
f	Number of counts of matching snip pairs.
g	Number of counts of matching snip pairs.
h	Number of counts of matching snip pairs.
i	Number of counts of matching snip pairs.

Details

The software automatically resolves the cases e=0 by circumventing the cubic equation. If the degree of the equation is lower additional copies of some solution will be made to produce the outputformat. The output format is a list of four vectors of copefficients. Each vector contains three complex numbers.

Value

output$A is a vector of length 3. output$B,Output$C, output$D is eighter of length 3. One potential solution is A[1],B[1],C[1],D[1].

```

---

optimalfrequency *Evaluate potential haplotypes.*

Description

Calculate the difference of a known haplotype and the resulting unordered pair of snip pairs.

Usage

```
optimalfrequency(mm, mmorg)
```

Arguments

mm	This is a contigency table of two haplotype snips. 2x2 matrix or ndata.frame
mmorg	This is a contigency table of two diplotype snips pairs.

Details

The average squared distance to the expected result 3x3 table is used as a T statistic. The p value not to be zero is calculated. The higher the p value the more exact is the haplotype.

Value

A list of values is returned.

result\$LK	Linkage disequilibrium
result\$Testvalue	The squared sitance multiplied by the number of entries in 3x3 matrix mmorg
result\$prSimilarByChange	The probability not o be equal to zero by change.
