

Package: IPEC (via r-universe)

September 10, 2024

Type Package

Title Root Mean Square Curvature Calculation

Version 1.1.0

Date 2024-01-13

Author Peijian Shi [aut, cre], Peter M. Ridland [aut], David A. Ratkowsky [aut], Yang Li [aut]

Maintainer Peijian Shi <pjshi@njfu.edu.cn>

Imports numDeriv (>= 2016.8-1.1), MASS

Description Calculates the RMS intrinsic and parameter-effects curvatures of a nonlinear regression model. The curvatures are global measures of assessing whether a model/data set combination is close-to-linear or not. See Bates and Watts (1980) <doi:10.1002/9780470316757> and Ratkowsky and Reddy (2017) <doi:10.1093/aesa/saw098> for details.

Depends R (>= 4.2.0)

IPEC-package	<i>Root Mean Square Curvature Calculation</i>
--------------	---

Description

Calculates the RMS intrinsic and parameter-effects curvatures of a nonlinear regression model. The curvatures are global measures of assessing whether a model/data set combination is close-to-linear or not. See Bates and Watts (1980) and Ratkowsky and Reddy (2017) for details.

Details

The DESCRIPTION file:

```

Package:      IPEC
Type:         Package
Title:        Root Mean Square Curvature Calculation
Version:      1.1.0
Date:         2024-01-13

Index of help topics:

IPEC-package	Root Mean Square Curvature Calculation
aic	Akaike Information Criterion (AIC) Calculation Function
biasIPEC	Bias Calculation Function
bic	Bayesian Information Criterion (BIC) Calculation Function
bootIPEC	Bootstrap Function for Nonlinear Regression
confcurves	Wald Confidence Curves and the Likelihood Confidence Curves
crops	Whole-plant biomass Data of 12 Species of Crops
curIPEC	RMS Curvature Calculation Function

derivIPEC	Derivative Calculation Function
fitIPEC	Nonlinear Fitting Function
isom	Data on Biochemical Oxygen Demand
leaves	Leaf Data of <i>_Parrotia subaequalis_</i> (Hamamelidaceae)
parinfo	Detailed Information of Estimated Model Parameters
shoots	Height Growth Data of Bamboo Shoots
skewIPEC	Skewness Calculation Function

Note

We are deeply thankful to Paul Gilbert and Jinlong Zhang for their invaluable help during creating this package. We also thank Linli Deng, Kurt Hornik and Lin Wang for their statistical and technical guidance in updating the package.

#####

```

aic

Akaike Information Criterion (AIC) Calculation Function

Description

Calculates the AIC value(s) of the object(s) obtained from using the [fitIPEC](#) function.

Usage

```
aic( object, ... )
```

Arguments

object	A fitted model object for which there exists the sample size (<code>sample.size</code> or <code>n</code>), estimate(s) of model parameter(s) (<code>par</code>), and residual sum of squares (RSS)
...	Optionally more fitted model objects

Details

$AIC = 2p - 2 \ln(L)$, where p represents the number of model parameter(s) plus 1 for the error, and $\ln(L)$ represents the maximum log-likelihood of the estimated model (Spiess and Neumeyer, 2010).

Value

There is an AIC value corresponding to one object, and there is a vector of AIC values corresponding to the multiple objects.

Note

When there are `sample.size` and `n` in object at the same time, the default of the sample size is `sample.size`, which is superior to `n`. With the sample size increasing, the number of model parameter(s) has a weaker influence on the value of AIC assuming that $\ln(RSS/n)$ is a constant.

biasIPEC

Bias Calculation Function

Description

Calculates the bias in the estimates of the parameters of a given nonlinear regression model.

Usage

```

biasIPEC(expr, theta, x, y, tol = 1e-16, method = "Richardson",
  method.args = list(eps = 1e-04, d = 0.11,
  zero.tol = sqrt(.Machine$double.eps/7e-07), r = 6, v = 2,
  show.details = FALSE), side = NULL)

```

Arguments

expr	A given nonlinear regression model
theta	A vector of parameters of the model
x	A vector or matrix of observations of independent variable(s)
y	A vector of observations of response variable
tol	The tolerance for detecting linear dependencies in the columns of a matrix for calculating its inverse. See the input argument of <code>tol</code> of the <code>solve</code> function in package base
method	It is the same as the input argument of <code>method</code> of the <code>hessian</code> function in package numDeriv
method.args	It is the same as the input argument of <code>method.args</code> of the <code>hessian</code> function in package numDeriv
side	It is the same as the input argument of <code>side</code> of the <code>jacobian</code> function in package numDeriv

Details

The defined model should have two input arguments: a parameter vector and an independent variable vector or matrix, e.g. `myfun <- function(P, x){...}`, where `P` represents the parameter vector and `x` represents the independent variable vector or matrix.

An absolute value of `percent.bias` (see below) in excess of **1%** appears to be a good rule of thumb for indicating nonlinear behavior (Ratkowsky 1983).

Value

bias	The bias
percent.bias	The percentage bias that is equal to $\text{bias}/\text{estimate} * 100\%$

Note

The current function can be applicable to nonlinear models with multiple independent variables.

bic

Bayesian Information Criterion (BIC) Calculation Function

Description

Calculates the BIC value(s) of the object(s) obtained from using the `fitIPEC` function.

Usage

```
bic( object, ... )
```

Arguments

<code>object</code>	A fitted model object for which there exists the sample size (<code>sample.size</code> or <code>n</code>), estimate(s) of model parameter(s) (<code>par</code>), and residual sum of squares (RSS)
<code>...</code>	Optionally more fitted model objects

Details

$BIC = p \ln(n) - 2 \ln(L)$, where p represents the number of model parameter(s) plus 1 for the error, n represents the sample size, and $\ln(L)$ represents the maximum log-likelihood of the estimated model (Spiess and Neumeyer, 2010).

Value

There is a BIC value corresponding to one object, and there is a vector of BIC values corresponding to the multiple objects.

Note

When there are `sample.size` and `n` in `object` at the same time, the default of the sample size is `sample.size`, which is superior to `n`. The BIC gives a higher penalty on the number of model parameters than the AIC.

bootIPEC

Bootstrap Function for Nonlinear Regression

Description

Generates the density distributions, standard errors, confidence intervals, covariance matrices and correlation matrices of parameters based on bootstrap replications.

Usage

```

bootIPEC( expr, x, y, ini.val, weights = NULL, control = list(),
          nboot = 200, CI = 0.95, fig.opt = TRUE, fold = 3.5,
          unique.num = 2, prog.opt = TRUE )

```

Arguments

expr	A given parametric model
x	A vector or matrix of observations of independent variable(s)
y	A vector of observations of response variable
ini.val	A vector or list of initial values of model parameters
weights	An optional vector of weights to be used in the fitting process. weights should be NULL or a numeric vector. If non-NULL, weighted least squares is used with weights weights; otherwise ordinary least squares is used.
control	A list of control parameters for using the <code>optim</code> function in package stats
nboot	The number of bootstrap replications
CI	The confidence level(s) of the required interval(s)
fig.opt	An option of drawing figures of the distributions of bootstrap values of parameters and figures of pairwise comparisons of bootstrap values
fold	A parameter removing the extreme bootstrap values of parameters
unique.num	The least number of sampled non-overlapping data points for carrying out a bootstrap nonlinear regression
prog.opt	An option of showing the running progress of bootstrap

Details

`ini.val` can be a vector or a list that has saved initial values for model parameters,

e.g. $y = \text{beta0} + \text{beta1} * x + \text{beta2} * x^2$,

`ini.val = list(beta0=seq(5, 15, len=2), beta1=seq(0.1, 1, len=9), beta2=seq(0.01, 0.05, len=5))`, which is similar to the usage of the input argument of `start` of `nls` in package `stats`.

In the `weights` argument option, the default is `weights = NULL`. In that case, ordinary least squares is used. The residual sum of squares (RSS) between the observed and predicted y values is minimized to estimate a model's parameters, i.e.,

$$\text{RSS} = \sum_{i=1}^n (y_i - \hat{y}_i)^2$$

where y_i and \hat{y}_i represent the observed and predicted y values, respectively; and n represents the sample size. If `weights` is a numeric vector, the weighted residual sum of squares is minimized, i.e.,

$$\text{RSS} = \sum_{i=1}^n w_i (y_i - \hat{y}_i)^2$$

where w_i is the i elements of `weights`.

`CI` determines the width of confidence intervals.

`fold` is used to delete the data whose differences from the median exceed a certain fold of the difference between 3/4 and 1/4 quantiles of the bootstrap values of a model parameter.

The default of `unique.num` is 2. That is, at least two non-overlapping data points randomly sampled from (x, y) are needed for carrying out a bootstrap nonlinear regression.

Value

<code>M</code>	The matrix saving the fitted results of all <code>nboot</code> bootstrap values of model parameters and goodness of fit
<code>perc.ci.mat</code>	The matrix saving the estimate, standard error, median, mean, and the calculated lower and upper limits of confidence interval based on the bootstrap percentile method
<code>bca.ci.mat</code>	The matrix saving the estimate, standard error, median, mean, and the calculated lower and upper limits of confidence interval based on the bootstrap BC_α method
<code>covar.mat</code>	The covariance matrix of parameters based on the bootstrap values when <code>nboot</code> > 1
<code>cor.mat</code>	The correlation matrix of parameters based on the bootstrap values when <code>nboot</code> > 1

Note

To obtain reliable confidence intervals of model parameters, more than **2000** bootstrap replications are recommended; whereas to obtain a reliable standard error of the estimate of a parameter, more than **30** bootstrap replications are sufficient (Efron and Tibshirani 1993). `bca.ci.mat` is recommended to show better confidence intervals of parameters than those in `perc.ci.mat`.

The outputs of model parameters will all be represented by θ_i , i from 1 to p , where p represents the number of model parameters. The letters of model parameters defined by users such as β_i will be automatically replaced by θ_i .

```

confcurves

Wald Confidence Curves and the Likelihood Confidence Curves

Description

Calculates the Wald confidence curves and the likelihood confidence curves of model parameters.

Usage

```

confcurves( expr, x, y, ini.val, weights = NULL, control=list(),
            fig.opt = TRUE, fold = 5, np = 20, alpha = seq(1, 0.001, by=-0.001),
            show.CI = NULL, method = "Richardson", method.args =
            list(eps = 1e-04, d = 0.11, zero.tol = sqrt(.Machine$double.eps/7e-07),
                 r = 6, v = 2, show.details = FALSE), side = NULL )

```

Arguments

<code>expr</code>	A given parametric model
<code>x</code>	A vector or matrix of observations of independent variable(s)
<code>y</code>	A vector of observations of response variable
<code>ini.val</code>	A vector or list of initial values of model parameters
<code>weights</code>	An optional vector of weights to be used in the fitting process. <code>weights</code> should be NULL or a numeric vector. If non-NULL, weighted least squares is used with weights <code>weights</code> ; otherwise ordinary least squares is used.
<code>control</code>	A list of control parameters for using the <code>optim</code> function in package stats
<code>fig.opt</code>	An option to determine whether to draw the confidence curves of each parameter
<code>fold</code>	The fold of $SE(\hat{\theta}_i)$ for controlling the width of the confidence interval of $\hat{\theta}_i$ that represents the estimate of the i th parameter
<code>np</code>	The number of data points for forming the lower or upper bounds of a likelihood confidence interval of $\hat{\theta}_i$, which controls the step size (i.e., δ) in the y coordinates of the likelihood confidence curves
<code>alpha</code>	The significance level(s) for calculating the x coordinate(s) of the $(1 - \alpha)100\%$ Wald confidence curves, which equals to $t_{\alpha/2}(n - p)$
<code>show.CI</code>	The $t_{\alpha/2}(n - p)$ value(s) associated with the confidence level(s) of each parameter to be showed, i.e., <code>c(0.80, 0.90, 0.95, 0.99)</code>
<code>method</code>	It is the same as the input argument of <code>method</code> of the <code>hessian</code> function in package numDeriv
<code>method.args</code>	It is the same as the input argument of <code>method.args</code> of the <code>hessian</code> function in package numDeriv
<code>side</code>	It is the same as the input argument of <code>side</code> of the <code>jacobian</code> function in package numDeriv

Details

For the $(1 - \alpha)100\%$ Wald confidence curves, the corresponding x and y coordinates are:

$$x = t_{\alpha/2}(n - p),$$

and

$$y = \hat{\theta}_i \pm t_{\alpha/2}(n - p) SE(\hat{\theta}_i),$$

where n denotes the number of the observations, p denotes the number of model parameters, and $SE(\hat{\theta}_i)$ denotes the standard error of the i th model parameter's estimate.

For the likelihood confidence curves (Cook and Weisberg, 1990), the corresponding x and y coordinates are:

$$x = \sqrt{\frac{RSS(\hat{\theta}^{(-i)}) - RSS(\hat{\theta})}{RSS(\hat{\theta})/(n - p)}},$$

where $\text{RSS}(\hat{\theta})$ represents the residual sum of squares for fitting the model with all model parameters; $\text{RSS}(\hat{\theta}^{(-i)})$ represents the residual sum of squares for fitting the model with the i th model parameter being fixed to be $\hat{\theta}_i \pm k \delta$. Here, k denotes the k th iteration, and δ denotes the step size, which equals

$$\delta = \frac{\hat{\theta}_i \pm \text{fold SE}(\hat{\theta}_i)}{\text{np}}$$

$$y = \hat{\theta}_i \pm k \delta.$$

Here, `fold` and `np` are defined by the user in the arguments.

For other arguments, please see the `fitIPEC` and `parinfo` functions for details.

Value

<code>partab</code>	The estimates, standard errors and confidence intervals of model parameters; also see the <code>parinfo</code> function
<code>parlist</code>	A list for the estimate, Wald interval curves and likelihood interval curves of each model parameter.

Note

In the value of `parlist`, there are the estimate (`pari`), the Wald interval curves (`WaldCI`), and the likelihood interval curves (`lhCI`) of the i th model parameter. In `WaldCI`, there are three columns. The first column, `tc`, represents $t_{\alpha/2}(n-p)$, the second and third columns, `LCI` and `UCI`, represent the lower and upper bounds of the $(1-\alpha)100\%$ Wald confidence intervals, respectively. In `lhCI`, there are six columns. The first and second columns, `x.lower` and `lhLCI`, represent the lower bounds of the likelihood confidence intervals and the corresponding x values, respectively; the third and fourth columns, `x.upper` and `lhUCI`, represent the upper bounds of the likelihood confidence intervals and the corresponding x values, respectively; the fifth and sixth columns, `RSS.lower` and `RSS.upper`, represent the values of the residual sum of squares of the lower bounds and those of the upper bounds, respectively. Please see Cook and Weisberg (1990) for details.

crops

Whole-plant biomass Data of 12 Species of Crops

Description

The whole-plant biomass data of 12 species of crops growing in northern China in 2011.

Usage

```
data(crops)
```

Details

In the data set, there are six columns: Code, CommonName, Date, Time, FM, and DM. Code is used to save the codes of crops; CommonName is used to save the common names of crops; Date is used to save the investigation date; Time is used to save the ages of crops from the sowing date (27 June, 2011) in days; FM is used to save the whole-plant fresh mass of crops in g; DM is used to save the whole-plant dry mass of crops in g.

Code = 1 represents sunflowers;

Code = 2 represents peanuts;

Code = 3 represents black soybeans;

Code = 4 represents soybeans;

Code = 5 represents kidney beans;

Code = 6 represents garden peas;

Code = 7 represents adzuki beans;

Code = 8 represents mungbeans;

Code = 9 represents cottons;

Code = 10 represents sweet sorghums;

Code = 11 represents corns;

Code = 12 represents Mexican corns.

curvIPEC

RMS Curvature Calculation Function

Description

Calculates the root mean square curvatures (intrinsic and parameter-effects curvatures) of a nonlinear regression model.

Usage

```

curvIPEC(expr, theta, x, y, tol = 1e-16, alpha = 0.05, method = "Richardson",
         method.args = list(eps = 1e-04, d = 0.11,
                             zero.tol = sqrt(.Machine$double.eps/7e-07),
                             r = 6, v = 2, show.details = FALSE), side = NULL)

```

Arguments

<code>expr</code>	A given parametric model
<code>theta</code>	A vector of parameters of the model
<code>x</code>	A vector or matrix of observations of independent variable(s)
<code>y</code>	A vector of observations of response variable
<code>tol</code>	The tolerance for detecting linear dependencies in the columns of a matrix in the QR decomposition. See the input argument of <code>tol</code> of the <code>qr</code> function in package base
<code>alpha</code>	Parameter controlling the significance level for testing the significance of a curvature
<code>method</code>	It is the same as the input argument of <code>method</code> of the <code>hessian</code> function in package numDeriv
<code>method.args</code>	It is the same as the input argument of <code>method.args</code> of the <code>hessian</code> function in package numDeriv
<code>side</code>	It is the same as the input argument of <code>side</code> of the <code>jacobian</code> function in package numDeriv

Details

This function was built based on the [hessian](#) and [jacobian](#) functions in package **numDeriv**, with reference to the [rms.curv](#) function in package **MASS**. However, it is more general without being limited by the [deriv3](#) function in package **stats** and **nls** class like the [rms.curv](#) function in package **MASS**. It mainly relies on package **numDeriv**. The users only need provide the defined model, the fitted parameter vector, and the observations of independent and response variables, they will obtain the curvatures. The input argument `theta` can be obtained using the [fitIPEC](#) function in the current package, and it also can be obtained using the other nonlinear regression functions.

Value

<code>rms.ic</code>	The root mean square intrinsic curvature
<code>rms.pec</code>	The root mean square parameter-effects curvature
<code>critical.c</code>	The critical curvature value

Note

The calculation precision of curvature mainly depends on the setting of `method.args`. The two important default values in the list of `method.args` are `d = 0.11`, and `r = 6`.

This function cannot be used to calculate the maximum intrinsic and parameter-effects curvatures.

derivIPEC

Derivative Calculation Function

Description

Calculates the Jacobian and Hessian matrices of model parameters at a number or a vector z .

Usage

```

derivIPEC(expr, theta, z, method = "Richardson",
          method.args = list(eps = 1e-04, d = 0.11,
                             zero.tol = sqrt(.Machine$double.eps/7e-07), r = 6, v = 2,
                             show.details = FALSE), side = NULL)

```

Arguments

<code>expr</code>	A given parametric model
<code>theta</code>	A vector of parameters of the model
<code>z</code>	A number or a vector where the derivatives are calculated
<code>method</code>	It is the same as the input argument of <code>method</code> of the hessian function in package numDeriv
<code>method.args</code>	It is the same as the input argument of <code>method.args</code> of the hessian function in package numDeriv
<code>side</code>	It is the same as the input argument of <code>side</code> of the jacobian function in package numDeriv

Details

The Hessian and Jacobian matrices are calculated at a number or a vector z , which represents a value of a single independent variable or a combination of different values of multiple independent variables. Note: z actually corresponds to a combination observation of x rather than all n observations. If there is only a predictor, z is a numerical value; there are several predictors, then z is a vector corresponding to one combination observation of those predictors.

Value

Jacobian The Jacobian matrix of parameters at z
 Hessian The Hessian matrix of parameters at z

fitIPEC

Nonlinear Fitting Function

Description

Estimates the parameters of a given parametric model using the `optim` function in package **stats**.

Usage

```
fitIPEC( expr, x, y, ini.val, weights = NULL, control = list(),
         fig.opt = TRUE, xlim = NULL, ylim = NULL, xlab = NULL, ylab = NULL )
```

Arguments

<code>expr</code>	A given parametric model
<code>x</code>	A vector or matrix of observations of independent variable(s)
<code>y</code>	A vector of observations of response variable
<code>ini.val</code>	A vector or list of initial values of model parameters
<code>weights</code>	An optional vector of weights to be used in the fitting process. <code>weights</code> should be <code>NULL</code> or a numeric vector. If non- <code>NULL</code> , weighted least squares is used with weights <code>weights</code> ; otherwise ordinary least squares is used.
<code>control</code>	A list of control parameters for using the <code>optim</code> function in package stats
<code>fig.opt</code>	An option to determine whether to draw the fitted curve
<code>xlim</code>	The shown range of the <i>x</i> -axis
<code>ylim</code>	The shown range of the <i>y</i> -axis
<code>xlab</code>	The label of the <i>x</i> -axis
<code>ylab</code>	The label of the <i>y</i> -axis

Details

The Nelder-Mead algorithm is the default in the `optim` function in package **stats**. The user can accurately estimate the model parameters by setting smaller relative convergence tolerance and larger maximum number of iterations in the input argument of `control`,

e.g. `control=list(trace=FALSE, reltol=1e-20, maxit=50000)`,
at the expense of the running speed.

`ini.val` can be a vector or a list that has saved initial values for model parameters,

e.g. `y = beta0 + beta1 * x + beta2 * x^2`,

`ini.val = list(beta0=seq(5, 15, len=2), beta1=seq(0.1, 1, len=9), beta2=seq(0.01, 0.05, len=5))`, which is similar to the usage of the input argument of `start` of `nls` in package **stats**.

In the `weights` argument option, the default is `weights = NULL`. In that case, ordinary least squares is used. The residual sum of squares (RSS) between the observed and predicted *y* values is minimized to estimate a model's parameters, i.e.,

$$\text{RSS} = \sum_{i=1}^n (y_i - \hat{y}_i)^2$$

where y_i and \hat{y}_i represent the observed and predicted *y* values, respectively; and n represents the sample size. If `weights` is a numeric vector, the weighted residual sum of squares is minimized, i.e.,

$$\text{RSS} = \sum_{i=1}^n w_i (y_i - \hat{y}_i)^2$$

where w_i is the *i* elements of weights.

Value

expr	The formula used
par	The vector of estimates of parameters
RSS	The residual sum of squares or the weighted residual sum of squares
R.sq	The coefficient of determination or the weighted coefficient of determination
n	The number of data points, namely the sample size

Note

This function can be applicable to a nonlinear parametric model with a single independent variable or with multiple independent variables.

R.sq is only used to help users intuitively judge whether the fitted curve seriously deviates from the actual observations. However, it should NOT be used to decide which of several competing models is the most appropriate (Pages 44–45 in Ratkowsky 1990). RSS and curvatures are among the suitable candidates to answer such a question.

#####

```

Description

Data on the reaction rate of the catalytic isomerization of *n*-pentane to isopentane versus the partial pressures of hydrogen, *n*-pentane, and isopentane.

Usage

```
data(isom)
```

Details

There are four columns in the data set:

'y' is the vector of experimental reaction rate (in 1/hr);

'x1' is the vector of partial pressure of hydrogen;

'x2' is the vector of partial pressure of *n*-pentane;

'x3' is the vector of partial pressure of isopentane.

Note

There were errors about the definitions of 'x2' and 'x3' in page 272 in Bates and Watts (1988). Here, we redefined them according to the paper of Carr (1960).

leaves

Leaf Data of Parrotia subaequalis (Hamamelidaceae)

Description

The data consist of the area, length and width of the leaves of 10 geographical populations of *P. subaequalis* collected in Southern China from July to September, 2016.

Usage

```
data(leaves)
```

Details

In the data set, there are four variables: PopuCode, Length, Width and Area. PopuCode is used to save the number codes of different geographical populations; Length is used to save the scanned leaf length data (cm); Width is used to save the scanned leaf width data (cm); Area is used to save the scanned leaf area data (cm squared).

parinfo

Detailed Information of Estimated Model Parameters

Description

Provides the estimates, standard errors, confidence intervals, Jacobian matrix, and the covariance matrix of model parameters.

Usage

```
parinfo(object, x, CI = 0.95, method = "Richardson",
        method.args = list(eps = 1e-04, d = 0.11,
        zero.tol = sqrt(.Machine$double.eps/7e-07), r = 6,
        v = 2, show.details = FALSE), side = NULL)
```

Arguments

object	A fitted model object for which there exist the model expression(<code>expr</code>), the sample size (<code>sample.size</code> or <code>n</code>), estimate(s) of model parameter(s) (<code>par</code>), and residual sum of squares (RSS)
x	A vector or a matrix of observations of independent variable(s)
CI	The confidence level(s) of the required interval(s)
method	It is the same as the input argument of <code>method</code> of the <code>hessian</code> function in package numDeriv
method.args	It is the same as the input argument of <code>method.args</code> of the <code>hessian</code> function in package numDeriv
side	It is the same as the input argument of <code>side</code> of the <code>jacobian</code> function in package numDeriv

Details

The object argument cannot be a list. It is a fitted model object from using the `fitIPEC` function.

Value

D	The Jacobian matrix of model parameters at all the x observations
partab	The estimates, standard errors and confidence intervals of model parameters
covmat	The covariance matrix of model parameters

Note

When there are `sample.size` and `n` in object at the same time, the default of the sample size is `sample.size`, which is superior to `n`.

Height Growth Data of Bamboo Shoots

Description

The height growth data of four species of bamboo at the Nanjing Forestry University campus in 2016.

Usage

```
data(shoots)
```

Details

In the data set, there are four variables: `Code`, `LatinName`, `x` and `y`. `Code` is used to save the number codes of different bamboo species; `LatinName` is used to save the Latin names of different bamboo species; `x` is used to save the investigation times (d) from a specific starting time of growth, and every bamboo has a different starting time of growth; `y` is used to save the measured aboveground height values (cm).

`Code = 1` represents *Phyllostachys iridescens*, and the starting time (namely $x = 0$) was defined as 12:00, 3rd April, 2016;

`Code = 2` represents *Phyllostachys mannii*, and the starting time (namely $x = 0$) was defined as 12:00, 4th April, 2016;

`Code = 3` represents *Pleioblastus maculatus*, and the starting time (namely $x = 0$) was defined as 12:00, 29th April, 2016;

`Code = 4` represents *Sinobambusa tootsik*, and the starting time (namely $x = 0$) was defined as 12:00, 18th April, 2016.

```

skewIPEC

*Skewness Calculation Function***Description**

Calculates the skewness in the estimates of the parameters of a given model.

Usage

```
skewIPEC( expr, theta, x, y, tol = sqrt(.Machine$double.eps), method = "Richardson",
          method.args = list(eps = 1e-04, d = 0.11,
                              zero.tol = sqrt(.Machine$double.eps/7e-07), r = 6, v = 2,
                              show.details = FALSE), side = NULL )
```

Arguments

expr	A given parametric model
theta	A vector of parameters of the model
x	A vector or matrix of observations of independent variable(s)
y	A vector of observations of response variable
tol	The tolerance for detecting linear dependencies in the columns of a matrix for calculating its inverse. See the input argument of <code>tol</code> of the ginv function in package MASS
method	It is the same as the input argument of <code>method</code> of the hessian function in package numDeriv
method.args	It is the same as the input argument of <code>method.args</code> of the hessian function in package numDeriv
side	It is the same as the input argument of <code>side</code> of the jacobian function in package numDeriv

Details

The defined model should have two input arguments: a parameter vector and an independent variable vector or matrix, e.g. `myfun <- function(P, x){...}`, where `P` represents the parameter vector and `x` represents the independent variable vector or matrix.

Let $|g_{1i}|$ be a measure of the skewness of the estimate of the i -th parameter. If $|g_{1i}| < \mathbf{0.1}$, the estimator $\hat{\theta}_i$ of parameter θ_i is very close-to-linear in behavior; if $\mathbf{0.1} \leq |g_{1i}| < \mathbf{0.25}$, the estimator is reasonably close-to-linear; if $|g_{1i}| \geq \mathbf{0.25}$, the skewness is very apparent; if $|g_{1i}| > \mathbf{1}$, the estimator is considerably nonlinear in behavior (Pages 27-28 in Ratkowsky 1990).

Value

skewness	The skewness
----------	--------------

Note

The current function can be applicable to nonlinear models with multiple independent variables.
