Type Package

Title Nonparametric Varying Coefficient Spike-and-Slab Lasso

Version 2.0

Date 2023-09-17

Author Ray Bai

Maintainer Ray Bai <raybaistat@gmail.com>

Description Fits Bayesian regularized varying coefficient models with the Nonparametric Varying Coefficient Spike-and-Slab Lasso (NVC-SSL) introduced by Bai et al. (2023) <[arXiv:1907.06477](#)>. Functions to fit frequentist penalized varying coefficients are also provided, with the option of employing the group lasso penalty of Yuan and Lin (2006) <[doi:10.1111/j.1467-9868.2005.00532.x](#)>, the group minimax concave penalty (MCP) of Breheny and Huang <[doi:10.1007/s11222-013-9424-2](#)>, or the group smoothly clipped absolute deviation (SCAD) penalty of Breheny and Huang (2015) <[doi:10.1007/s11222-013-9424-2](#)>.

NVC_frequentist	<i>Fits frequentist penalized nonparametric varying coefficient (NVC) models</i>
-----------------	--

Description

This function implements frequentist penalized nonparametric varying coefficient (NVC) models. It supports the following penalty functions: the group lasso penalty of Yuan and Lin (2006), the group minimax concave penalty (MCP) of Breheny and Huang (2015), and the group smoothly clipped absolute deviation (SCAD) penalty of Breheny and Huang (2015). This function solves a penalized regression problem of the form,

$$\operatorname{argmax}_{\gamma} \frac{1}{N} \ell(\gamma) + \operatorname{pen}_{\lambda}(\gamma),$$

where N is the total number of observations, $\ell(\gamma)$ is the loss function, and $\operatorname{pen}_{\lambda}(\cdot)$ is a penalty function with regularization parameter $\lambda > 0$. Since the objective function is rescaled by $1/N$, the penalty λ is typically smaller than the spike hyperparameter λ_0 used by the NVC_SSL function. The BIC criterion is used to select the optimal tuning parameter λ .

Usage

```
NVC_frequentist(y, t, X, n_basis=8, penalty=c("gLASSO", "gSCAD", "gMCP"),
               lambda=NULL, include_intercept=TRUE)
```

Arguments

<code>y</code>	$N \times 1$ vector of response observations $y_{11}, \dots, y_{1m_1}, \dots, y_{n1}, \dots, y_{nm_n}$
<code>t</code>	$N \times 1$ vector of observation times $t_{11}, \dots, t_{1m_1}, \dots, t_{n1}, \dots, t_{nm_n}$
<code>X</code>	$N \times p$ design matrix with columns $[X_1, \dots, X_p]$, where the k th column contains the entries $x_{ik}(t_{ij})$'s
<code>n_basis</code>	number of basis functions to use. Default is <code>n_basis=8</code> .
<code>penalty</code>	string specifying which penalty function to use. Specify "gLASSO" for group lasso, "gSCAD" for group SCAD, or "gMCP" for group MCP.
<code>lambda</code>	grid of tuning parameters. If <code>lambda</code> is not specified (i.e. <code>lambda=NULL</code>), then the program automatically chooses a grid for <code>lambda</code> . Note that since the objective function is scaled by $1/N$, the automatically chosen grid for <code>lambda</code> typically consists of smaller values than the default grid for <code>lambda0</code> used by the function NVC_SSL.
<code>include_intercept</code>	Boolean variable for whether or not to include an intercept function $\beta_0(t)$ in the estimation. Default is <code>include_intercept=TRUE</code> .

Value

The function returns a list containing the following components:

<code>t_ordered</code>	all N time points ordered from smallest to largest. Needed for plotting.
<code>classifications</code>	$p \times 1$ vector of indicator variables, where "1" indicates that the covariate is selected and "0" indicates that it is not selected. These classifications are determined by the optimal lambda chosen from BIC. Note that this vector does not include an intercept function.
<code>beta_hat</code>	$N \times p$ matrix of the estimates for varying coefficient functions $\beta_k(t)$, $k = 1, \dots, p$, using the optimal lambda chosen from BIC. The k th column in the matrix is the k th estimated function at the observation times in <code>t_ordered</code> .
<code>beta0_hat</code>	estimate of the intercept function $\beta_0(t)$ at the observation times in <code>t_ordered</code> for the optimal lambda chosen from BIC. This is not returned if <code>include_intercept = FALSE</code> .
<code>gamma_hat</code>	estimated basis coefficients (needed for prediction) for the optimal lambda.
<code>lambda_min</code>	the individual lambda which minimizes the BIC. If only one value was originally passed for lambda, then this just returns that lambda.
<code>lambda0_all</code>	grid of all L regularization parameters in lambda. Note that since the objective function is scaled by $1/N$ for the penalized frequentist methods in the <code>NVC_frequentist</code> function, the <code>lambda_all</code> grid that is chosen automatically by <code>NVC_frequentist</code> typically consists of smaller values than the default values in the <code>lambda0_all</code> grid for <code>NVC_SSL</code> .
<code>BIC_all</code>	$L \times 1$ vector of BIC values corresponding to all L entries in <code>lambda_all</code> . The l th entry corresponds to the l th entry in <code>lambda_all</code> .
<code>beta_est_all_lambda</code>	list of length L of the estimated varying coefficients $\beta_k(t)$, $k = 1, \dots, p$, corresponding to all L lambdas in <code>lambda_all</code> . The l th entry corresponds to the l th entry in <code>lambda_all</code> .
<code>beta0_est_all_lambda</code>	$N \times L$ matrix of estimated intercept function $\beta_0(t)$ corresponding to all L entries in <code>lambda_all</code> . The l th column corresponds to the l th entry in <code>lambda_all</code> . This is not returned if <code>include_intercept=FALSE</code> .
<code>gamma_est_all_lambda</code>	$dp \times L$ matrix of estimated basis coefficients corresponding to all entries in <code>lambda_all</code> . The l th column corresponds to the l th entry in <code>lambda_all</code> .
<code>classifications_all_lambda</code>	$p \times L$ matrix of classifications corresponding to all the entries in <code>lambda_all</code> . The l th column corresponds to the l th entry in <code>lambda_all</code> .
<code>iters_to_converge</code>	number of iterations it took for the group ascent algorithm to converge for each entry in <code>lambda_all</code> . The l th entry corresponds to the l th entry in <code>lambda_all</code> .

```

NVC_predict *Prediction for nonparametric varying coefficient (NVC) models*

Description

This is a function to predict the responses $y(t_{new})$ for new subjects at new time points t_{new} with new covariates X_{new} . The function accepts an estimated NVC model that was fit using either the `NVC_SSL` or `NVC_frequentist` functions and returns the predicted $y(t)$'s. This function can be used for either out-of-sample predictions or for in-sample predictions if the "new" subjects are the same as the ones used to obtain the fitted NVC model.

Usage

```
NVC_predict(NVC_mod, t_new, id_new, X_new)
```

Arguments

<code>NVC_mod</code>	an object with a fitted NVC model returned by the <code>NVC_SSL</code> or <code>NVC_frequentist</code> function
<code>t_new</code>	vector of new observation times
<code>id_new</code>	vector of new labels, where a label corresponds to one of the new subjects
<code>X_new</code>	new design matrix with columns $[X_1, \dots, X_p]$ where the k th column corresponds to the k th covariate. <code>X_new</code> must have the p columns, i.e. the same number of varying coefficients estimated by <code>NVC_mod</code> .

Value

The function returns a list containing the following components:

<code>id</code>	vector of each i th subject's label
<code>time</code>	vector of each j th observation time for each i th subject
<code>y_pred</code>	vector of predicted responses corresponding to each j th observation time for each i th subject

NVC_SSL

Nonparametric Varying Coefficient Spike-and-Slab Lasso (NVC-SSL)

Description

This function implements the Nonparametric Varying Coefficient Spike-and-Slab Lasso (NVC-SSL) model of Bai et al. (2023) for high-dimensional NVC models. The function returns the MAP estimator for the varying coefficients $\beta_k(t)$, $k = 1, \dots, p$, obtained from the ECM algorithm described in Bai et al. (2023). The BIC criterion is used to select the optimal spike hyperparameter λ_0 .

If the user specifies `return_CI=TRUE`, then this function will also return the 95 percent pointwise posterior credible intervals for the varying coefficients $\beta_k(t)$, $k = 1, \dots, p$, obtained from Gibbs

sampling. If the number of covariates p is large, then the user can additionally use the approximate MCMC algorithm introduced in Bai et al. (2023) (`approx_MCMC=TRUE`) which is much faster than the exact Gibbs sampler and gives higher simultaneous coverage.

Finally, this function returns the number of iterations and the runtime for the ECM algorithms and MCMC algorithms which can be used for benchmarking and timing comparisons.

Usage

```
NVC_SSL(y, t, id, X, n_basis=8,
        lambda0=seq(from=300,to=10,by=-10), lambda1=1,
        a=1, b=ncol(X), c0=1, d0=1, nu=n_basis+2, Phi=diag(n_basis),
        include_intercept=TRUE, tol=1e-6, max_iter=100,
        return_CI=FALSE, approx_MCMC=FALSE,
        n_samples=1500, burn=500, print_iter=TRUE)
```

Arguments

<code>y</code>	$N \times 1$ vector of response observations $y_{11}, \dots, y_{1m_1}, \dots, y_{n1}, \dots, y_{nm_n}$
<code>t</code>	$N \times 1$ vector of observation times $t_{11}, \dots, t_{1m_1}, \dots, t_{n1}, \dots, t_{nm_n}$
<code>id</code>	$N \times 1$ vector of labels, where each unique label corresponds to one of the subjects
<code>X</code>	$N \times p$ design matrix with columns $[X_1, \dots, X_p]$, where the k th column contains the entries $x_{ik}(t_{ij})$'s
<code>n_basis</code>	number of basis functions to use. Default is <code>n_basis=8</code> .
<code>lambda0</code>	grid of spike hyperparameters. Default is to tune <code>lambda0</code> from the grid of decreasing values (300, 290, ..., 20, 10).
<code>lambda1</code>	slab hyperparameter. Default is <code>lambda1=1</code> .
<code>a</code>	hyperparameter in $B(a, b)$ prior on mixing proportion θ . Default is $a = 1$.
<code>b</code>	hyperparameter in $B(a, b)$ prior on mixing proportion θ . Default is $b = p$.
<code>c0</code>	hyperparameter in Inverse-Gamma($c_0/2, d_0/2$) prior on measurement error variance σ^2 . Default is $c_0 = 1$.
<code>d0</code>	hyperparameter in Inverse-Gamma($c_0/2, d_0/2$) prior on measurement error variance σ^2 . Default is $d_0 = 1$.
<code>nu</code>	degrees of freedom for Inverse-Wishart prior on Ω . Default is <code>n_basis+2</code> .
<code>Phi</code>	scale matrix in the Inverse-Wishart prior on Ω . Default is the identity matrix.
<code>include_intercept</code>	Boolean variable for whether or not to include an intercept function $\beta_0(t)$ in the estimation. Default is <code>include_intercept=TRUE</code> .
<code>tol</code>	convergence criteria for the ECM algorithm. Default is <code>tol=1e-6</code> .
<code>max_iter</code>	maximum number of iterations to run ECM algorithm. Default is <code>max_iter=100</code> .
<code>return_CI</code>	Boolean variable for whether or not to return the 95 percent pointwise credible bands. Set <code>return_CI=TRUE</code> if posterior credible bands are desired.

approx_MCMC	Boolean variable for whether or not to run the approximate MCMC algorithm instead of the exact MCMC algorithm. If approx_MCMC=TRUE, then an approximate MCMC algorithm is used. Otherwise, if approx_MCMC=FALSE, the exact MCMC algorithm is used. This argument is ignored if return_CI=FALSE.
n_samples	number of MCMC samples to save for posterior inference. The default is to save n_samples=1500. This is ignored if return_CI=FALSE.
burn	number of initial MCMC samples to discard during the warm-up period. Default is burn=500. This is ignored if return_CI=FALSE.
print_iter	Boolean variable for whether or not to print the progress of the algorithms. Default is print_iter=TRUE.

Value

The function returns a list containing the following components:

t_ordered	all N time points ordered from smallest to largest. Needed for plotting
classifications	$p \times 1$ vector of indicator variables, where "1" indicates that the covariate is selected and "0" indicates that it is not selected. These classifications are determined by the optimal λ_{BIC} chosen from BIC. Note that this vector does not include an intercept function.
beta_hat	$N \times p$ matrix of the MAP estimates for varying coefficient functions $\beta_k(t)$, $k = 1, \dots, p$, using the optimal λ_{BIC} chosen from BIC. The k th column in the matrix is the k th estimated function at the observation times in t_ordered.
beta0_hat	MAP estimate of the intercept function $\beta_0(t)$ at the observation times in t_ordered for the optimal λ_{BIC} chosen from BIC. This is not returned if include_intercept = FALSE.
gamma_hat	MAP estimates of the basis coefficients (needed for prediction) for the optimal λ_{BIC} .
beta_post_mean	$N \times p$ matrix of the posterior mean estimates of the varying coefficient functions. The k th column in the matrix is the k th posterior mean estimate for $\beta_k(t)$ at the observation times in t_ordered. This is not returned if return_CI=FALSE.
beta_CI_lower	$N \times p$ matrix of the lower endpoints of the 95 percent pointwise posterior credible interval (CI) for the varying coefficient functions. The k th column in the matrix is the lower endpoint for the CI of $\beta_k(t)$ at the observation times in t_ordered. This is not returned if return_CI=FALSE.
beta_CI_upper	$N \times p$ matrix of the upper endpoints of the 95 percent pointwise posterior credible interval (CI) for the varying coefficient functions. The k th column in the matrix is the upper endpoint for the CI of $\beta_k(t)$ at the observation times in t_ordered. This is not returned if return_CI=FALSE.
beta0_post_mean	Posterior mean estimate of the intercept function $\beta_0(t)$ at the observation times in t_ordered. This is not returned if return_CI=FALSE.
beta0_CI_lower	Lower endpoints of the 95 percent pointwise posterior credible intervals (CIs) for the intercept function $\beta_0(t)$ at the observation times in t_ordered. This is not returned if return_CI=FALSE.

beta0_CI_upper	Upper endpoints of the 95 percent pointwise posterior credible intervals (CIs) for the intercept function $\beta_0(t)$ at the observation times in <code>t_ordered</code> . This is not returned if <code>return_CI=FALSE</code> .
gamma_post_mean	Posterior mean estimates of all the basis coefficients. This is not returned if <code>return_CI=FALSE</code> .
gamma_CI_lower	Lower endpoints of the 95 percent posterior credible intervals for the basis coefficients. This is not returned if <code>return_CI=FALSE</code> .
gamma_CI_upper	Upper endpoints of the 95 percent posterior credible intervals for the basis coefficients. This is not returned if <code>return_CI=FALSE</code> .
post_incl	$p \times 1$ vector of estimated posterior inclusion probabilities (PIPs) for each of the varying coefficients. The k th entry in <code>post_incl</code> is the PIP for β_k . This is not returned if <code>return_CI=FALSE</code> .
lambda0_min	the individual <code>lambda0</code> which minimizes the BIC. If only one value was originally passed for <code>lambda0</code> , then this just returns that <code>lambda0</code> .
lambda0_all	grid of all L regularization parameters in <code>lambda0</code> . Note that since the objective function is scaled by $1/N$ for the penalized frequentist methods in the <code>NVC_frequentist</code> function, the <code>lambda0_all</code> grid that is chosen automatically by <code>NVC_frequentist</code> typically consists of smaller values than the default values in the <code>lambda0_all</code> grid for <code>NVC_SSL</code> .
BIC_all	$L \times 1$ vector of BIC values corresponding to all L entries in <code>lambda0_all</code> . The l th entry corresponds to the l th entry in <code>lambda0_all</code> .
beta_est_all_lambda0	list of length L of the estimated varying coefficients $\beta_k(t)$, $k = 1, \dots, p$, corresponding to all L lambdas in <code>lambda0_all</code> . The l th entry corresponds to the l th entry in <code>lambda0_all</code> .
beta0_est_all_lambda0	$N \times L$ matrix of estimated intercept function $\beta_0(t)$ corresponding to all L entries in <code>lambda0_all</code> . The l th column corresponds to the l th entry in <code>lambda0_all</code> . This is not returned if <code>include_intercept=FALSE</code> .
gamma_est_all_lambda0	$dp \times L$ matrix of estimated basis coefficients corresponding to all entries in <code>lambda0_all</code> . The l th column corresponds to the l th entry in <code>lambda0_all</code> .
classifications_all_lambda0	$p \times L$ matrix of classifications corresponding to all the entries in <code>lambda0_all</code> . The l th column corresponds to the l th entry in <code>lambda0_all</code> .
ECM_iters_to_converge	number of iterations it took for the ECM algorithm to converge for each entry in <code>lambda0_all</code> . The l th entry corresponds to the l th entry in <code>lambda0_all</code> .
ECM_runtimes	$L \times 1$ vector of the number of seconds it took for the ECM algorithm to converge for each entry in <code>lambda0_all</code> . The l th entry corresponds to the l th entry in <code>lambda0_all</code> .
gibbs_runtime	number of minutes it took for the Gibbs sampling algorithm to run for the total number of MCMC iterations given in <code>gibbs_iters</code>
gibbs_iters	total number of MCMC iterations run for posterior inference

```

SimulatedData

Simulated data for illustration

Description

This is a simulated dataset for illustration. It contains a total of $N = 436$ observations at irregularly spaced time points for $n = 50$ subjects. There are $p = 100$ covariates.

Usage

```
data(SimulatedData)
```

Details

This simulated dataset contains $N = 436$ observations for $n = 50$ subjects, with $p = 100$ covariates. The first column y gives the response variables, the second column t gives the observation times, the third column id gives the unique IDs for each of the 50 subjects, and columns 4-103 (x_1, \dots, x_{100}) give the covariate values.

This synthetic dataset is a slight modification from Experiment 2 in Section 5.1 of Bai et al. (2023). We use $p = 100$ for illustration, instead of $p = 500$ as in the paper.
