Version 1.4.0

Date 2017-05-18

Title Generalized Discrimination Score

Description This is an implementation of the Generalized Discrimination Score (also known as Two Alternatives Forced Choice Score, 2AFC) for various representations of forecasts and verifying observations. The Generalized Discrimination Score is a generic forecast verification framework which can be applied to any of the following verification contexts: dichotomous, polychotomous (ordinal and nominal), continuous, probabilistic, and ensemble. A comprehensive description of the Generalized Discrimination Score, including all equations used in this package, is provided by Mason and Weigel (2009) <[doi:10.1175/MWR-D-10-05069.1](https://doi.org/10.1175/MWR-D-10-05069.1)>.

afc-package

Generalized Discrimination Score 2AFC

Description

This package is a collection of routines to calculate the "generalized discrimination score", which is also known as "two alternatives forced-choice score" or short: "2AFC-score". The 2AFC is a generic forecast verification framework which can be applied to any of the following verification contexts: dichotomous, polychotomous (ordinal and nominal), continuous, probabilistic, and ensemble. A comprehensive description of the 2AFC-score, including all equations used in this package, is provided by Mason and Weigel (2009).

Details

The master routine is `afc`. For a given set of observation and forecast data, and for a specified verification context, `afc` calls the appropriate functions which are necessary to calculate the 2AFC score.

Why the 2AFC-score? There are numerous reasons for calculating forecast verification scores, and considerable attention has been given to designing and analyzing the properties of scores that can be used for scientific purposes. Much less attention has been given to scores that may be useful for administrative reasons, such as communicating changes in forecast quality to bureaucrats, and providing indications of forecast quality to the general public. The 2AFC test a scoring procedure that is sufficiently generic to be useable on forecasts ranging from simply "yes"/"no" forecasts of dichotomous outcomes to continuous variables, and can be used with deterministic or probabilistic forecasts without seriously reducing the more complex information when available. Although, as

with any single verification score, the 2AFC has limitations, it does have broad intuitive appeal in that the expected score of an unskilled set of forecasts (random guessing or perpetually identical forecasts) is 50%, and is interpretable as an indication of how often the forecasts are correct, even when the forecasts are expressed probabilistically and/or the observations are not discrete.

 afc

Calculate Generalized Discrimination Score 2AFC

Description

This is the master routine for the calculation the Generalized Discrimination Score (aka Two-Alternatives Forced Choice Score - 2AFC) as described in the Paper of Mason and Weigel (2009). This routine requires, as input, datasets of forecasts and corresponding observations, as well as a specification of the verification context. The routine checks whether the input data are consistent with the verification context, then calls the appropriate function to calculate the 2AFC, and finally returns the 2AFC skill value.

Usage

```
afc(obsv, fcst, obsv.type, fcst.type, m = 0, m2 = 0)
```

Arguments

| | |
|------|---|
| obsv | Vector of observations. The required format depends on the specific verification context. More details below. |
| fcst | Vector or two-dimensional array of forecasts. The required format depends on the specific verification context. More details below. |

| | |
|------------------|---|
| <i>obsv.type</i> | Character specifying the type of the observations. Possible values: "d" (dichotomous), "m" (polychotomous with ordinal categories), "n" (polychotomous with nominal categories), "c" (continuous). |
| <i>fcst.type</i> | Character specifying the type of the forecasts. Possible values: "d" (dichotomous), "m" (polychotomous with ordinal categories), "n" (polychotomous with nominal categories), "p" (probabilistic), "c" (continuous) and "e" (ensemble). |
| <i>m</i> | Number of observation or forecast categories (only required if <i>obsv.type</i> or <i>fcst.type</i> equals "m" or "n") |
| <i>m2</i> | Number of forecast categories (only required if both <i>obsv.type</i> and <i>fcst.type</i> equal "m"). The number of observation categories is then specified by the argument <i>m</i> above. |

Details

Depending on the specific verification context (i.e. the choice for *obsv.type* and *fcst.type*), this routine calls the appropriate function(s) to calculate the 2AFC score. The following combinations of *obsv.type* and *fcst.type* are possible: (1) "d-d"; (2) "d-m"; (3) "d-p"; (4) "d-c"; (5) "d-e"; (6) "m-m"; (7) "m-p"; (8) "m-c"; (9) "m-e"; (10) "n-n"; (11) "n-p"; (12) "c-c"; (13) "c-e". The required format of the input data *obsv* and *fcst* depends on the verification context:

(1) "d-d":

obsv: vector with dichotomous observations (values in 0,1)

fcst: vector of same length as *obsv* with dichotomous forecasts (values in 0,1)

(2) "d-m":

obsv: vector with dichotomous observations (values in 0,1)

fcst: vector of same length as *obsv* with polychotomous forecasts (values in 1,...,m)

(3) "d-p":

obsv: vector with dichotomous observations (values in 0,1)

fcst: vector of same length as *obsv* with forecast probabilities for the event to happen

(4) "d-c":

obsv: vector with dichotomous observations (values in 0,1)

fcst: vector of same length as *obsv* with real-valued forecasts

(5) "d-e":

obsv: vector with dichotomous observations (values in 0,1)

fcst: two-dimensional array with ensemble forecasts; $\dim(\text{fcst})[1] = \text{length}(\text{obsv})$; $\dim(\text{fcst})[2] = \text{ensemble size}$.

(6) "m-m":

obsv: vector with polychotomous observations (values in 1,...,m)

fcst: vector of same length as *obsv* with polychotomous forecasts (values in 1,...,m2)

(7) "m-p":

obsv: vector with polychotomous observations (values in 1,...,m)

fcst: two-dimensional array with forecast probabilities for the m categories; $\dim(\text{fcst})[1] = \text{length}(\text{obsv})$;
 $\dim(\text{fcst})[2] = m$

(8) "m-c":

obsv: vector with polychotomous observations (values in 1,...,m)

fcst: vector of same length as *obsv* with real-valued forecasts

(9) "m-e":

obsv: vector with polychotomous observations (values in 1,...,m)

fcst: two-dimensional array with ensemble forecasts; $\dim(\text{fcst})[1] = \text{length}(\text{obsv})$; $\dim(\text{fcst})[2] =$
ensemble size.

(10) "n-n":

obsv: vector with polychotomous observations (values in 1,...,m)

fcst: vector of same length as *obsv* with polychotomous forecasts (values in 1,...,m)

(11) "n-p":

Same as "m-p".

(12) "c-c":

obsv: vector with real-valued observations

fcst: vector of same length as *obsv* with real-valued forecasts

(13) "c-e":

obsv: vector with real-valued observations

fcst: two-dimensional array with ensemble forecasts; $\dim(\text{fcst})[1] = \text{length}(\text{obsv})$; $\dim(\text{fcst})[2] =$
ensemble size.

afc.cc

2AFC For Continuous Observations And Continuous Forecasts

Description

Routine to calculate the Generalized Discrimination Score (aka Two-Alternatives Forced Choice Score 2AFC) for the situation of continuous observations and continuous forecasts

Usage

```
afc.cc(obsv, fcst)
```

Arguments

| | |
|------|---|
| obsv | vector with real-valued observations |
| fcst | vector of same length as <i>obsv</i> with real-valued forecasts |

Details

This routine applies Eq.22 of Mason and Weigel (2009) to calculate the 2AFC.

Value

p. afc Value of Generalized Discrimination (2AFC) Score

2AFC For Continuous Observations And Ensemble Forecasts

Description

Routine to calculate the Generalized Discrimination Score (aka Two-Alternatives Forced Choice Score 2AFC) for the situation of continuous observations and ensemble forecasts

Usage

```
afc.ce(obsv, fcst)
```

Arguments

obsv vector with real-valued observations
fcst two-dimensional array with ensemble forecasts; dim(fcst)[1] = length(obsv);
dim(fcst)[2] = ensemble size

Details

This routine first ranks the ensemble forecasts (see [rank.ensembles](#)) and then calculates the 2AFC-score with Eq.22 of Mason and Weigel (2009).

Value

p. afc Value of Generalized Discrimination (2AFC) Score

|--------|---|
| afc.me | <i>2AFC For Ordinal Polychotomous Observations And Ensemble Forecasts</i> |
|--------|---|

Description

Routine to calculate the Generalized Discrimination Score (aka Two-Alternatives Forced Choice Score 2AFC) for the situation of polychotomous observations (ordinal) and ensemble forecasts

Usage

```
afc.me(obsv, fcst, m = 3)
```

Arguments

| | |
|------|--|
| obsv | vector with polychotomous observations (values in 1,...,m) |
| fcst | two-dimensional array with ensemble forecasts; dim(fcst)[1] = length(obsv); dim(fcst)[2] = ensemble size |
| m | number of observation categories (default = 3) |

Details

This routine first ranks the ensemble forecasts (see [rank.ensembles](#)) and then calculates the 2AFC-score with Eq.18 of Mason and Weigel (2009).

Value

| | |
|--------|--|
| p. afc | Value of Generalized Discrimination (2AFC) Score |
|--------|--|

Example Data of Continuous Observations and Continuous Forecasts

Description

Continuous observations (obsv) and continuous forecasts (fcst) of the Nino-3.4 index for January 1961-2000. The forecast data stem from model runs initialized using data for the preceding August 1960-1999.

Format

The format is:
 List of 3
 \ \$ years: int [1:40] 1961 1962 1963 1964 1965 1966 1967 1968 1969 1970 ...
 \ \$ obsv : num [1:40] 26.2 26.2 25.9 27.4 25.8 ...
 \ \$ fcst : num [1:40] 26.5 26.3 26.6 27.7 25.8 ...

Details

The forecast data are from the coupled ocean-atmosphere model of the Centre National de Recherches Meteorologiques (CNRM) of Meteo France and were generated as part of the "Development of a European Multimodel Ensemble System for Seasonal to Interannual Prediction (DEMETER)" project (Palmer et al. 2004). Note that also the examples presented in the 2AFC paper by Mason and Weigel (2009) are based on these data.

rank.ensembles

*Rank Ensembles***Description**

Routine to rank a set of given ensemble forecasts according to their "value"

Usage

rank.ensembles(fcst)

Arguments

fcst two-dimensional array with ensemble forecasts; $\dim(\text{fcst})[1]$ = number of ensemble forecasts; $\dim(\text{fcst})[2]$ = number of ensemble members

Details

This routine ranks a set of ensemble forecasts according to their "value". The higher the "value" of an ensemble forecasts, the higher the rank. The following principle is applied: Assume two ensembles A and B are to be ranked. Without loss of generality, we define $A > B$ if the probability of a random ensemble member of A being larger than a random ensemble member of B exceeds 0.5. This probability is calculated by a 2AFC-like approach based on Eq. 8 of Mason and Weigel (2009). By pairwise comparison of all ensembles, the final ranking is obtained.

Value

ranks vector with the ranks of the ensemble forecasts

Author(s)

Andreas Weigel, Federal Office of Meteorology and Climatology, MeteoSwiss, Zurich, Switzerland

Examples

```
#Load a set of ensemble forecasts
data(cnrm.nino34.ce)
fcst = cnrm.nino34.ce$fcst

#Rank ensemble forecasts
rank.ensembles(fcst)
```
