

# Package: bayesLife (via r-universe)

December 6, 2024

**Type** Package

**Title** Bayesian Projection of Life Expectancy

**Version** 5.3-1

**Date** 2024-12-05

**Description** Making probabilistic projections of life expectancy for all countries of the world, using a Bayesian hierarchical model <doi:10.1007/s13524-012-0193-x>. Subnational projections are also supported.

**Depends** bayesTFR (>= 7.3-0), R (>= 3.5.0)

**Imports** wpp2019, hett, car, coda, data.table

**Suggests** wpp2017, wpp2015, wpp2012, wpp2010

**License** GPL-3 | file LICENSE

**URL** <https://bayespop.csss.washington.edu>

**LazyData** false

**NeedsCompilation** yes

**Author** Hana Sevcikova [cre, aut], Adrian Raftery [aut], Jennifer Chunn [aut]

**Maintainer** Hana Sevcikova <hanas@uw.edu>

**Repository** CRAN

**Date/Publication** 2024-12-06 10:30:10 UTC

**Config/pak/sysreqs** cmake make libicu-dev

bayesLife-package	<i>Bayesian Projection of the Life Expectancy</i>
-------------------	---

---

## Description

Collection of functions for making probabilistic projections of the life expectancy for all countries of the world, using a Bayesian hierarchical model and the United Nations demographic time series. Projections on a subnational level are also supported.

## Details

The projection follows a method developed by Chunn et al (2010, 2013). It uses historical data provided by the United Nations to simulate a posterior distribution of the life expectancy for all countries in the world simultaneously.

The package is implemented in a similar way as the **bayesTFR** package and thus, many functions have their equivalents in **bayesTFR**. The main functions of the **bayesLife** package are:

- [run.e0.mcmc](#): Runs a Markov Chain Monte Carlo (MCMC) simulation for one or more chains, possibly in parallel. It results in a posterior sample of the MCMC parameters. Existing simulation runs can be resumed using [continue.e0.mcmc](#).
- [e0.predict](#): Using the posterior parameter samples it derives posterior trajectories of the life expectancy for all countries.
- [e0.jmale.predict](#): Given existing outputs of [e0.predict](#) for female life expectancy, this function estimates and predicts a joint male life expectancy as described in Raftery et al (2014).
- [e0.predict.subnat](#): Given existing projections on national level, it generates projections on a subnational level, for both, female and male (Sevcikova and Raftery 2021).

A number of functions analyzing results are included in the package:

- [e0.trajectories.plot](#): Shows the posterior trajectories for a given country, including their median and given probability intervals.
- [e0.trajectories.table](#): Shows the posterior trajectories for a given country in a tabular form.
- [e0.map](#) and [e0.map.gvis](#): Show a world map of life expectancy for a given projection period.
- [e0.DLcurve.plot](#): Shows the posterior curves of the double logistic function used in the simulation, including their median and given probability intervals.
- [e0.partraces.plot](#) and [e0.partraces.cs.plot](#): Plot the MCMC traces of country-independent parameters and country-specific parameters, respectively.
- [e0.pardensity.plot](#) and [e0.pardensity.cs.plot](#): Plot the posterior density of the MCMCs for country-independent parameters and country-specific parameters, respectively.
- [summary.bayesLife.mcmc.set](#): Summary function for the MCMC results.
- [summary.bayesLife.prediction](#): Summary function for the prediction results.

For MCMC diagnostics, function [e0.coda.list.mcmc](#) creates an object of type “mcmc.list” that can be used with the **coda** package. Furthermore, function [e0.diagnose](#) analyzes the MCMCs using the Raftery diagnostics implemented in the **coda** package and gives information about parameters that did not converge. Function [e0.dl.coverage](#) computes a goodness of fit of the double logistic function.

Existing simulation results can be accessed using the [get.e0.mcmc](#) function. An existing prediction can be accessed via [get.e0.prediction](#). Existing predictions on a subnational level can be accessed via [get.rege0.prediction](#).

For a table with countries included in the mcmc or prediction object, the function [get.countries.table](#) can be used in the same way as in **bayesTFR**.

Historical data are taken from one of the packages **wpp2019** (default), **wpp2017**, **wpp2015**, **wpp2012** or **wpp2010**, depending on users settings. For more recent data, package **wpp2022** can be installed from Github (@PPgp).

**Note**

There is a directory `ex-data` shipped with the package which contains results from an example simulation, containing one chain with 60 iterations. The Example section below shows how these results were created. These data are used in Example sections throughout the manual. The user can either reproduce the data in her/his local directory, or use the ones from the package.

bayesLife.mcmc

*MCMC Simulation Object*

---

**Description**

MCMC simulation object `bayesLife.mcmc` containing information about one MCMC chain. A set of such objects belonging to the same simulation together with a `bayesLife.mcmc.meta` object constitute a `bayesLife.mcmc.set` object.

**Details**

An object `bayesLife.mcmc` points to a place on disk (element `output.dir`) where MCMC results from all iterations are stored. They can be retrieved to the memory using `get.e0.mcmc(...)`.

The object is in standard cases not to be manipulated by itself, but rather as part of a `bayesLife.mcmc.set` object.

**Value**

A `bayesLife.mcmc` object contains parameters of the Bayesian hierarchical model, more specifically, their initial values (all names with the suffix `.ini`) and values from the last iteration. These are:

`Triangle/Triangle.ini`, `lambda/lambda.ini` - world parameters, containing four values each. They correspond to model parameters  $\Delta_1, \dots, \Delta_4$  and  $\lambda_1, \dots, \lambda_4$ , respectively.

`k/k.ini`, `z/z.ini`, `omega/omega.ini`, `lambda.k/lambda.k.ini`, `lambda.z/lambda.z.ini` - world parameters, containing one value each. They correspond to model parameters  $k$ ,  $z$ ,  $\omega$ ,  $\lambda_k$ , and  $\lambda_z$ , respectively.

`Triangle.c` - country-specific parameter  $\Delta_1^c, \dots, \Delta_4^c$  with four values for each country, i.e. an  $4 \times C$  matrix where  $C$  is the number of countries.

`k.c`, `z.c` - country-specific parameters  $k^c$  and  $z^c$  (1d arrays of length  $C$ ).

Furthermore, the object contains components:

<code>iter</code>	Total number of iterations the simulation was started with.
<code>finished.iter</code>	Number of iterations that were finished. Results from the last finished iteration are stored in the parameters above.
<code>length</code>	Length of the MCMC stored on disk. It differs from <code>finished.iter</code> only if <code>thin</code> is larger than one.
<code>thin</code>	Thinning interval used when simulating the MCMCs.
<code>id</code>	Identifier of this chain.
<code>output.dir</code>	Subdirectory (relative to <code>output.dir</code> in the <code>bayesLife.mcmc.meta</code> object) where results of this chain are stored.
<code>traces</code>	This is a placeholder for keeping whole parameter traces in the memory. If the processing operates in a low memory mode, it will be 0. It can be filled in using the function <code>get.e0.mcmc(..., low.memory=FALSE)</code> . In such a case, <code>traces</code> is a $I \times J$ array where $I$ is the MCMC length and $J$ is the number of parameters.
<code>traces.burnin</code>	Burnin used to retrieve the traces, i.e. how many stored iterations are missing from the beginning in the <code>traces</code> array comparing to the 'raw' traces on the disk.
<code>rng.state</code>	State of the random number generator at the end of the last finished iteration.
<code>meta</code>	Object of class <code>bayesLife.mcmc.meta</code> used for simulation of this chain.

`run.e0.mcmc`, `get.e0.mcmc`, `bayesLife.mcmc.set`, `bayesLife.mcmc.meta`

## Examples

```
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
# loads traces from one chain
m <- get.e0.mcmc(sim.dir, low.memory = FALSE, burnin = 40, chain.ids = 1)
# should have 20 rows, since 60 iterations in total minus 40 burnin
dim(e0.mcmc(m, 1)$traces)
summary(m)
```

---

bayesLife.mcmc.meta     *MCMC Simulation Meta Object*

---

## Description

Simulation meta object `bayesLife.mcmc.meta` used by all chains of the same MCMC simulation. It contains information that is common to all chains. It is a part of a [bayesLife.mcmc.set](#) object.

## Details

The object is in standard cases not to be manipulated by itself, but rather as part of a [bayesLife.mcmc.set](#) object.

## Value

A `bayesLife.mcmc.meta` object stores values of the various input arguments of the [run.e0.mcmc](#) function. These are `sex`, `nr.chains`, `start.year`, `present.year`, `wpp.year`, `my.e0.file`, `compression.type`. Furthermore, it contains components:

<code>e0.matrix.all</code>	A $q \times n$ matrix with the United Nations life expectancy estimates. $q$ is number of years, $n$ is number of countries (see <code>nr.countries</code> below). The first $n_e$ columns correspond to countries included in the MCMC estimation (see <code>nr.countries.estimation</code> below), where $n_e \leq n$ . The order of the countries corresponds to the order of countries in the element <code>regions</code> and <code>regionsDT</code> , see below.
<code>e0.matrix</code>	Like <code>e0.matrix.all</code> , but it has NA values for years that were excluded from the estimation due to setting the <code>start.year</code> and <code>present.year</code> argument, and the 'last.observed' column (see Details in <a href="#">run.e0.mcmc</a> ).
<code>d.ct</code>	A difference <code>e0</code> matrix of size $(q - 1) \times n$ . Each element $x_{t,i}$ is a difference $y_{t+1,i} - y_{t,i}$ where $y$ denotes elements of the <code>e0.matrix</code> . Outliers are set to NA.
<code>loessSD</code>	Matrix of the same dimension as <code>d.ct</code> . It contains values of the <code>loess_sd</code> dataset at the <code>e0</code> levels of <code>e0.matrix</code> . See also <a href="#">compute.loess</a> .
<code>nr.countries</code>	Number of countries included in the <code>e0</code> matrices.
<code>nr.countries.estimation</code>	Number of countries included in the MCMC estimation. It must be smaller or equal to <code>nr.countries</code> .
<code>Tc.index</code>	A list with one element per country. For each country, it contains the index within <code>e0.matrix</code> where the observed historical data are not NA, i.e. it points to the data used in the estimation.

regions	List of arrays of length <code>nr.countries</code> . These are: name - Region name for each country. code - Region code for each country. area_name - Area name for each country. area_code - Area code for each country. country_name - Array of country names. country_code - Array of country codes. Any country indices in the <code>bayesLife.mcmc.meta</code> object are derived from this component.
regionsDT	Like <code>regions</code> but for convenience it is a <code>data.table</code> object. A country in <i>i</i> -th row of this table has <code>e0</code> data stored in the <i>i</i> -th column of <code>e0.matrix</code> .
output.dir	Directory for storing simulation output.
mcmc.options	List of various options used in the estimation. See <a href="#">e0mcmc.options</a> .
country.bounds	List of country-specific bounds of the various parameter priors, as constructed from the <code>country.overwrites</code> option (see <a href="#">e0mcmc.options</a> ).
suppl.data	If supplemental data were used in the simulation (i.e. start year was set prior to 1950), this is a list containing information about the additional data. It has the following components of the same form as described above, but related only to the additional data: <code>e0.matrix</code> , <code>regions</code> , <code>regionsDT</code> , <code>Tc.index</code> , <code>nr.countries</code> , <code>d.ct</code> , <code>loessSD</code> . In addition, it has the vectors <code>index.from.all.countries</code> - a vector of size <code>nr.countries</code> (all countries) where each element is an index to the supplemental data, i.e. a match from <code>regions\$country_code</code> to <code>suppl.data\$regions\$country_code</code> . <code>index.to.all.countries</code> - a vector of size <code>suppl.data\$nr.countries</code> (additional countries) where each element is an index to all data, i.e. a match from <code>suppl.data\$regions\$country_code</code> to <code>regions\$country_code</code> .

```
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
m <- get.e0.mcmc(sim.dir)
summary(m, meta.only = TRUE)
names(m$meta)
```

---

 compute.loess

*Computing Residuals and Fitting Local Polynomial Regression*

---

### Description

Functions for computing residuals from the observed life expectancy and MCMC estimation, and fitting a local polynomial regression.

### Usage

```
compute.residuals(sim.dir, burnin = 1000)
```

```
compute.loess(sim.dir = NULL, burnin = 1000, residuals = NULL)
```

### Arguments

sim.dir	Directory with the MCMC estimation. In <code>compute.loess</code> , it is only used if <code>residuals</code> is not given.
burnin	Number of (unthinned) iterations to be discarded. In <code>compute.loess</code> , it is only used if <code>residuals</code> is not given.
residuals	Residuals can be computed outside of the <code>compute.loess</code> function and passed as the <code>residuals</code> argument. If not given, the <code>compute.loess</code> function calls <code>compute.residuals</code> internally, in which case <code>sim.dir</code> must be given.

### Details

The Bayesian hierarchical model for life expectancy uses a lowess curve as a multiplier of the variance. The dataset is stored in the package as the `loess_sd` dataset. These functions can be used to re-compute this `loess_sd` dataset. In such a case, the simulation should be run with the argument `constant.variance = TRUE` (in `run.e0.mcmc`).

The residuals are computed for each country as the absolute differences between the observed life expectancy increases and the mean of the estimated double logistic function at the corresponding life expectancy level.

### Value

`compute.residuals` returns a data frame with columns 'x' (life expectancy levels) and 'y' (absolute residuals).

`compute.loess` also returns a data frame with columns 'x' and 'y', where 'x' is the same as before (with added a minimum and maximum) and 'y' is the local polynomial fit with constant tails.

### Author(s)

Hana Sevcikova

**See Also**

[run.e0.mcmc](#)

**Examples**

```
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
resid <- compute.residuals(sim.dir, burnin = 30)
lws <- compute.loess(residuals = resid)

# plot residuals and loess
plot(resid$x, resid$y, ylim = c(0, 4))
lines(lws$x, lws$y, col = "red")
```

---

convert.e0.trajectories

*Converting Trajectories of Life Expectancy into ASCII Files*

---

**Description**

Converts trajectories of the life expectancy stored in a binary format into two CSV files of a UN-specific format.

**Usage**

```
convert.e0.trajectories(dir = file.path(getwd(), "bayesLife.output"),
  n = 1000, subdir = "predictions", output.dir = NULL, verbose = FALSE)
```

**Arguments**

dir	Directory containing the prediction object. It should correspond to the <code>output.dir</code> argument of the <a href="#">e0.predict</a> function.
n	Number of trajectories to be stored. It can be either a single number or the word "all" in which case all available trajectories are converted.
subdir	Name of subdirectory of <code>dir</code> containing the prediction.
output.dir	Directory in which the resulting files will be stored. If <code>NULL</code> the same directory is used as for the prediction. Otherwise, if the directory contains joint predictions for both sexes, the outputs are stored into subdirectories 'F' and 'M'.
verbose	Logical switching log messages on and off.

**Details**

The function creates two files per sex. One is called "ascii\_trajectories.csv", it is a comma-separated table with the following columns:

**"LocID"**: country code

**"Period"**: prediction interval, e.g. 2015-2020

“**Year**”: middle year of the prediction interval

“**Trajectory**”: identifier of the trajectory

“**e0**”: life expectancy

The second file is called “ascii\_trajectories\_wide.csv”, it is also a comma-separated table and it contains the same information as above but in a ‘transposed’ format. I.e. the data for one country are ordered in columns, thus, there is one column per country. The country columns are ordered alphabetically.

If *n* is smaller than the total number of trajectories, the trajectories are selected using equal spacing.

### Note

This function is automatically called from the `e0.predict` function, therefore in standard cases it will not be needed to call it directly. However, it can be useful for example, if different number of trajectories are to be converted, without having to re-run the prediction.

### Author(s)

Hana Sevcikova

[write.e0.projection.summary](#), [e0.predict](#)

### Examples

```
## Not run:
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
pred.dir <- file.path(getwd(), "exampleLEpred")

# stores 10 trajectories out of 30 (60-30) into
# exampleLEpred/predictions/ascii_trajectories.csv (for female)
# and exampleLEpred/predictions/joint_male/ascii_trajectories.csv (for male)
e0.predict(sim.dir = sim.dir, output.dir = pred.dir,
           burnin = 30, save.as.ascii = 10, verbose = TRUE)

# stores all 30 trajectories into the current directory
convert.e0.trajectories(dir = pred.dir, n = "all", output.dir = ".", verbose = TRUE)

# Note: If the output.dir argument in e0.predict is omitted,
# call convert.e0.trajectories with dir = sim.dir

## End(Not run)
```

---

e0.coda.list.mcmc      *Conversion to coda's Objects*

---

## Description

The functions convert MCMC traces (simulated using `run.e0.mcmc`) into objects that can be used with the **coda** package.

## Usage

```
e0.coda.list.mcmc(mcmc.list = NULL, country = NULL, chain.ids = NULL,
  sim.dir = file.path(getwd(), "bayesLife.output"),
  par.names = NULL, par.names.cs = NULL, low.memory = FALSE, ...)
```

```
## S3 method for class 'bayesLife.mcmc'
coda.mcmc(mcmc, country = NULL, par.names = NULL, par.names.cs = NULL, ...)
```

## Arguments

<code>mcmc.list</code>	List of <code>bayesLife.mcmc</code> objects, or an object of class <code>bayesLife.mcmc.set</code> or <code>bayesLife.prediction</code> . If it is NULL, the MCMCs are loaded from <code>sim.dir</code> . Either <code>mcmc.list</code> or <code>sim.dir</code> must be given.
<code>mcmc</code>	Object of class <code>bayesLife.mcmc</code> .
<code>country</code>	Country name or code. It is used in connection with the <code>par.names.cs</code> argument (see below).
<code>chain.ids</code>	Vector of chain identifiers. By default, all chains available in the <code>mcmc.list</code> object are included.
<code>sim.dir</code>	Directory with the MCMC simulation results. Only used if <code>mcmc.list</code> is NULL.
<code>par.names</code>	Names of country-independent parameters to be included.
<code>par.names.cs</code>	Names of country-specific parameters to be included. The argument <code>country</code> is used to filter out traces that correspond to a specific country. If <code>country</code> is not given, for each parameter, traces for all countries are included.
<code>low.memory</code>	Logical indicating if the function should run in a memory-efficient mode.
<code>...</code>	Additional arguments passed to the <b>coda</b> 's <code>mcmc</code> function, such as <code>burnin</code> and <code>thin</code> .

## Value

The function `e0.coda.list.mcmc` returns an object of class "mcmc.list". The function `coda.mcmc` returns an object of class "mcmc", both defined in the **coda** package.

## Author(s)

Hana Sevcikova

**See Also**

[e0.partraces.plot](#) for plotting the MCMC traces and [summary.bayesLife.mcmc.set](#).

**Examples**

```
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
coda.list <- e0.coda.list.mcmc(sim.dir = sim.dir, country = "France", burnin = 30)
summary(coda.list)
```

---

e0.diagnose	<i>Convergence Diagnostics for Markov Chain Monte Carlo of Life Expectancy</i>
-------------	--

---

**Description**

Function `e0.diagnose` runs convergence diagnostics of existing MCMCs, using the `raftery.diag` function from the `coda` package.

**Usage**

```
e0.diagnose(sim.dir, thin = 225, burnin = 10000, express = FALSE,
            country.sampling.prop = NULL, keep.thin.mcmc = FALSE, verbose = TRUE)
```

**Arguments**

<code>sim.dir</code>	Directory with the MCMC simulation results.
<code>thin</code>	Thinning interval.
<code>burnin</code>	Number of iterations to be discarded from the beginning of the parameter traces.
<code>express</code>	Logical. If TRUE, the convergence diagnostics is run only on the country-independent parameters. If FALSE, the country-specific parameters are included in the diagnostics. The number of countries can be controlled by <code>country.sampling.prop</code> .
<code>country.sampling.prop</code>	Proportion of countries that are included in the diagnostics. If it is NULL and <code>express=FALSE</code> , all countries are included. Setting here a number between 0 and 1, one can limit the number of countries which are then randomly sampled. Note that for long MCMCs, this argument may significantly influence the runtime of this function.
<code>keep.thin.mcmc</code>	Logical. If TRUE the thinned traces used for computing the diagnostics are stored on disk (see <a href="#">create.thinned.e0.mcmc</a> ).
<code>verbose</code>	Logical switching log messages on and off.

**Details**

The function invokes the `e0.raftery.diag` function separately for country-independent parameters and for country-specific parameters. It results in two possible states: red, i.e. it did not converge, and green, i.e. it converged. The resulting object is stored in `{sim.dir}/diagnostics/bayesLife.convergence_{thin}_{burnin}.rda` and can be accessed using the function `get.e0.convergence`.

Function `has.mcmc.converged` from the **bayesTFR** package can be used to check if the existing diagnostics converged.

**Value**

`e0.diagnose` returns an object of class `bayesLife.convergence` with components:

<code>result</code>	Table containing all not-converged parameters. Its columns include ‘Total iterations needed’ and ‘Remaining iterations’.
<code>lresult.country.independent</code>	Number of rows in <code>result</code> that correspond to country-independent parameters. These rows are grouped at the beginning of the table.
<code>country.independent</code>	Result of <code>e0.raftery.diag</code> processed on country-independent parameters.
<code>country.specific</code>	Result of <code>e0.raftery.diag</code> processed on country-specific parameters.
<code>iter.needed</code>	Number of additional iterations suggested in order to achieve convergence.
<code>iter.total</code>	Total number of iterations of the original unthinned set of chains.
<code>use.nr.traj</code>	Suggestion for number of trajectories in generating predictions.
<code>burnin</code>	Burnin used.
<code>thin</code>	Thinning interval used.
<code>status</code>	Vector of character strings containing the result status. Possible values: ‘green’, ‘red’.
<code>mcmc.set</code>	Object of class <code>bayesLife.mcmc.set</code> that corresponds to the original set of MCMCs on which the diagnostics was run.
<code>thin.mcmc</code>	If <code>keep.thin.mcmc</code> is TRUE, it is an object of class <code>bayesLife.mcmc.set</code> that corresponds to the thinned mcmc set on which the diagnostics was run, otherwise NULL.
<code>express</code>	Value of the input argument <code>express</code> .
<code>nr.countries</code>	Vector with elements used - number of countries used in this diagnostics, and total - number of countries that this <code>mcmc.set</code> object was estimated on.

e0.dl.coverage

*Goodness of Fit of the Double Logistic Function*

---

**Description**

The function computes coverage, i.e. the ratio of observed data fitted within the given probability intervals of the predictive posterior distribution of the double logistic function, as well as the root mean square error of the simulation.

**Usage**

```
e0.dl.coverage(sim.dir, pi = c(80, 90, 95), burnin = 10000, verbose = TRUE)
```

**Arguments**

sim.dir	Directory with the MCMC simulation results. If a prediction and its corresponding thinned mcmc are available in the simulation directory, those are taken for assessing the goodness of fit.
pi	Probability interval. It can be a single number or an array.
burnin	Burnin. Only relevant if sim.dir does not contain thinned chains.
verbose	Logical switching log messages on and off.

**Value**

List with the same components as [tfr.dl.coverage](#).

**Note**

To see the fit visually per country, use [e0.DLcurve.plot\(..., predictive.distr=TRUE,...\)](#).

**Author(s)**

Hana Sevcikova

e0.DLcurve.plot	<i>Plotting Posterior Distribution of the Double Logistic Function of Life Expectancy</i>
-----------------	---

---

### Description

The functions plot the posterior distribution of the double logistic function used in the simulation, including their median and given probability intervals.

### Usage

```
e0.DLcurve.plot(mcmc.list, country, burnin = NULL, pi = 80,
  e0.lim = NULL, nr.curves = 20, predictive.distr = FALSE, ylim = NULL,
  xlab = "e(0)", ylab = "5-year gains", main = NULL, show.legend = TRUE,
  col = c('black', 'red', "#00000020"), ...)
```

```
e0.DLcurve.plot.all(mcmc.list = NULL, sim.dir = NULL,
  output.dir = file.path(getwd(), "DLcurves"),
  output.type = "png", burnin = NULL, verbose = FALSE, ...)
```

```
e0.parDL.plot(mcmc.set, country = NULL, burnin = NULL, lty = 2,
  ann = TRUE, ...)
```

```
e0.world.dlcurves(x, mcmc.list, burnin = NULL, ...)
```

```
e0.country.dlcurves(x, mcmc.list, country, burnin = NULL, ...)
```

### Arguments

mcmc.list	List of <a href="#">bayesLife.mcmc</a> objects, an object of class <a href="#">bayesLife.mcmc.set</a> or of class <a href="#">bayesLife.prediction</a> . In case of <code>e0.DLcurve.plot.all</code> if it is NULL, it is loaded from <code>sim.dir</code> .
mcmc.set	Object of class <a href="#">bayesLife.mcmc.set</a> or <a href="#">bayesLife.prediction</a> .
country	Name or numerical code of a country. It can also be given as ISO-2 or ISO-3 characters.
burnin	Number of iterations to be discarded from the beginning of parameter traces.
pi	Probability interval. It can be a single number or an array.
e0.lim	It can be a tuple of the minimum and maximum life expectancy to be shown in the plot. If NULL, it takes the minimum of observed data and 40, and the maximum of observed data and 90.
nr.curves	Number of curves to be plotted. If NULL, all curves are plotted.
predictive.distr	Logical. If TRUE, an error term is added to each trajectory.
ylim, xlab, ylab, main, lty	Graphical parameters passed to the plot function.

show.legend	Logical determining if the legend should be shown.
col	Vector of colors in this order: 1. observed data points, 2. quantiles, 3. trajectories
...	Additional graphical parameters. In addition, any arguments from <code>e0.DLcurve.plot</code> except <code>country</code> can be passed to <code>e0.DLcurve.plot.all</code> .
sim.dir	Directory with the simulation results. Only relevant, if <code>mcmc.list</code> is <code>NULL</code> .
output.dir	Directory into which resulting graphs are stored.
output.type	Type of the resulting files. It can be “png”, “pdf”, “jpeg”, “bmp”, “tiff”, or “postscript”.
verbose	Logical switching log messages on and off.
x	e0 values for which the double logistic should be computed.
ann	Logical if parameters should be annotated.

### Details

`e0.DLcurve.plot` plots double logistic curves for the given country. `e0.DLcurve.plot.all` creates such plots for all countries and stores them in `output.dir`. Parameters passed to the double logistic function are either thinned traces created by the `e0.predict` function (if `mcmc.list` is an object of class `bayesLife.prediction`), or they are selected by equal spacing from the MCMC traces. In the former case, `burnin` is set automatically; in the latter case, `burnin` defaults to 0 since such object has already been “burned”. If `nr.curves` is smaller than 2000, the median and probability intervals are computed on a sample of 2000 equally spaced data points, otherwise on all plotted curves.

Function `e0.parDL.plot` draws the means of the DL parameters as vertical and horizontal lines. The lines are added to the current graphical device and annotated if `ann` is `TRUE`. If `country` is `NULL`, the mean of world parameters are drawn.

Function `e0.world.dlcurves` returns the DL curves of the hierarchical distribution. Function `e0.country.dlcurves` returns DL curves for a given country. If `mcmc.list` is a prediction object, `burnin` should not be given, as such object has already been “burned”.

### Value

`e0.world.dlcurves` and `e0.country.dlcurves` return a matrix of size  $N \times M$  where  $N$  is the number of trajectories and  $M$  is the number of values of  $x$ .

### Author(s)

Hana Sevcikova

### Examples

```
## Not run:
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
mcmc.set <- get.e0.mcmc(sim.dir = sim.dir)
e0.DLcurve.plot(mcmc.set, country = "Japan", burnin = 40)
e0.parDL.plot(mcmc.set, "Japan")
```

```
# add the median of the hierarchical DL curves
x <- seq(40, 90, length = 100)
world <- e0.world.dlcurves(x, mcmc.set, burnin = 40)
qw <- apply(world, 2, median)
lines(x, qw, col = 'blue')

## End(Not run)
```

---

e0.gap.plot

*Posterior Distribution of Gaps in Female and Male Life Expectancy*

---

### Description

The functions plot the posterior distribution of the gaps between female and male life expectancy, modeled and predicted using a model described in Lalic (2011) and Raftery, Lalic & Gerland (2014). This can be done for one country (`e0.gap.plot`) or for all countries (`e0.gap.plot.all`).

### Usage

```
e0.gap.plot(e0.pred, country, e0.pred2 = NULL, pi = c(80, 95),
  nr.traj = 0, xlim = NULL, ylim = NULL, type = "b",
  xlab = "Year", ylab = "Gap in life expectancy", main = NULL,
  show.legend = TRUE, ...)

e0.gap.plot.all(e0.pred, output.dir = file.path(getwd(), "e0gaps"),
  output.type = "png", verbose = FALSE, ...)
```

### Arguments

<code>e0.pred</code>	Object of class <code>bayesLife.prediction</code> containing female projections. If <code>e0.pred2</code> is not given, then this object must contain the ‘joint.male’ component, generated using the <code>e0.jmale.predict</code> function.
<code>country</code>	Name or numerical code of a country. It can also be given as ISO-2 or ISO-3 characters.
<code>e0.pred2</code>	Object of class <code>bayesLife.prediction</code> containing male projections. By default the male projections is taken from the joint female-male projections in <code>e0.pred</code> , see above.
<code>pi</code>	Probability interval. It can be a single number or an array.
<code>nr.traj</code>	Number of trajectories to be plotted.
<code>xlim, ylim, type, xlab, ylab, main</code>	Graphical parameters passed to the plot function.
<code>show.legend</code>	Logical controlling whether the legend should be drawn.
<code>output.dir</code>	Directory into which resulting graphs are stored.
<code>output.type</code>	Type of the resulting files. It can be “png”, “pdf”, “jpeg”, “bmp”, “tiff”, or “postscript”.

verbose            Logical switching log messages on and off.  
 ...                Additional graphical parameters. In addition, for `e0.gap.plot.all`, ... contains any of the arguments of `e0.gap.plot`.

```

---

`e0.jmale.estimate`            *Estimation of the Joint Female-Male Model*

---

### Description

The function estimates the joint female-male model of life expectancy, as described in Raftery et al. (2014, 2012) and Lalic (2011). It consist of two equations with t-distributed errors, see Details below.

### Usage

```
e0.jmale.estimate(mcmc.set, countries.index = NULL,
  estDof.eq1 = TRUE, start.eq1 = list(dof = 2), max.e0.eq1 = 83,
  estDof.eq2 = TRUE, start.eq2 = list(dof = 2),
  constant.gap.eq2 = TRUE, include.suppl.gap = FALSE,
  my.e0.file = NULL, my.locations.file = NULL,
  verbose = FALSE)
```

### Arguments

`mcmc.set`            Object of class `bayesLife.mcmc.set` containing estimation results of female life expectancy.  
`countries.index`      Index of countries (within the `mcmc.set` object) to be included in the estimation. By default, all countries included in the estimation of `mcmc.set` are used.

estDof.eq1, estDof.eq2	Logical, controlling whether the degrees of freedom of the first and second equation, respectively, should be estimated. If it is FALSE the degrees of freedom are set using the arguments start.eq1 and start.eq2, respectively.
start.eq1, start.eq2	Argument start of the <code>tlm</code> function of the <code>hett</code> package, which is applied to the first and second equation of the model, respectively. It is a list of possibly four named components, ("beta", "lambda", "dof", "omega"), for the location, scale, degrees of freedom parameters and random scale effects respectively. If estDof.eq1 (estDof.eq2) is FALSE, the "dof" component must be given.
max.e0.eq1	Maximum female life expectancy of records included in the estimation of the first equation (parameter $M$ in Details below).
constant.gap.eq2	Logical. If TRUE the coefficient of the second equation ( $\gamma_1$ ) is set to one and the standard deviation is estimated under the assumption of normal distribution.
include.suppl.gap	If TRUE data prior 1950 are used in the estimation of the gap model.
my.e0.file	File name containing user-specified male time series for one or more countries. The function replaces the corresponding country data from the WPP dataset by values in this file. Only columns are replaced that match column names of the WPP dataset.
my.locations.file	File name containing user-specified locations if different from the default <code>UNlocations</code> dataset. It should be the same file as passed to <code>run.e0.mcmc</code> for female life expectancy.
verbose	Logical switching log messages on and off. If TRUE summary results from the <code>tlm</code> function of both equations are shown.

## Details

The joint female-male life expectancy model is a model for estimating gaps  $G$  between female and male life expectancy. It consists of two parts, see Equation (1) in Raftery et al. (2012):

1. If  $l_{c,t} \leq M$ , then

$$G_{c,t} = \beta_0 + \beta_1 l_{c,1953} + \beta_2 G_{c,t-1} + \beta_3 l_{c,t} + \beta_4 (l_{c,t} - 75)_+ + \epsilon_{c,t}$$

where  $\epsilon_{c,t}$  is iid  $t(\mu = 0, \sigma_1^2, \nu_1)$ .

2. If  $l_{c,t} > M$ , then

$$G_{c,t} = \gamma_1 G_{c,t-1} + \epsilon_{c,t}$$

where  $\epsilon_{c,t}$  is iid  $t(\mu = 0, \sigma_2^2, \nu_2)$ .

Here,  $t$  is the time and  $c$  is the country index.  $G_{c,t}$  is the gap for country  $c$  at time  $t$  and  $l_{c,t}$  is the female life expectancy for country  $c$  at time  $t$ .  $M$  can be set in the `max.e0.eq1` argument.

Using the `tlm` function of the `hett` package, the function estimates the coefficients  $\beta_i$  ( $i = 1, \dots, 4$ ) and  $\gamma_1$ , as well as parameters  $\sigma_j$  ( $j = 1, 2$ ) and optionally the degrees of freedom  $\nu_j$  ( $j = 1, 2$ ). If `constant.gap.eq2` is TRUE,  $\gamma_1$  is set to 1 and  $\epsilon_{c,t}$  is iid  $N(\mu = 0, \sigma_2^2)$ .

The `mcmc.set` object should be a `bayesLife.mcmc.set` object obtained from a simulation of a female life expectancy. Note that since only the observed data and no MCMC results are used in

this estimation, the `mcmc.set` object can be obtained from a toy simulation such as in the example below. The function extracts observed data from this object and treats them as  $l_{c,t}$ . For the male historical time series, the function takes the male WPP dataset (`e0M`) from the same `wpp` package as the female data, and possibly partly replaces the male dataset by any user-specified data given in `my.e0.file`.

## Value

List with the components, `eq1` and `eq2`, each containing estimation results from the first and second equation, respectively. These are:

<code>coefficients</code>	Estimated coefficients $\beta_i$ .
<code>sigma</code>	Parameter $\sigma_j$ .
<code>dof</code>	Degrees of freedom $\nu_j$ . If <code>estDof.eq1</code> ( <code>estDof.eq2</code> ) is TRUE this parameter is estimated, otherwise it is set to the value of <code>start.eq1\$dof</code> ( <code>start.eq2\$dof</code> ).

```

---

e0.jmale.predict      *Prediction of the Joint Female-Male Model*

---

### Description

Prediction of the joint female-male model of life expectancy, as described in Raftery et al. (2014, 2012) and Lalic (2011).

### Usage

```
e0.jmale.predict(e0.pred, estimates = NULL, gap.lim = c(0, 18),
  max.e0.eq1.pred = 86, my.e0.file = NULL, my.locations.file = NULL,
  save.as.ascii = 1000, resample.outrange = TRUE, verbose = TRUE, ...)
```

### Arguments

e0.pred	Object of class <code>bayesLife.prediction</code> containing female projections of life expectancy.
estimates	List of the same structure as returned by <code>e0.jmale.estimate</code> , containing the model estimation results. If it is not given, the <code>e0.jmale.estimate</code> function is invoked.
gap.lim	Vector of length two giving the minimum and maximum bounds for the female-male life expectancy gaps. See argument <code>resample.outrange</code> for two ways of handling gaps that fall outside of this range.
max.e0.eq1.pred	Maximum female life expectancy for male projections handled by the first equation (parameter $M$ in Equation (1) in Raftery et al. (2012)).
my.e0.file	File name containing user-specified male time series for one or more countries. The function replaces the corresponding country data from the WPP dataset by values in this file. Only columns are replaced that match column names of the WPP dataset.
my.locations.file	File name containing user-specified locations if different from the default <code>UNlocations</code> dataset. It should be the same file as passed to <code>run.e0.mcmc</code> for female life expectancy.
save.as.ascii	Either a number determining how many trajectories should be converted into an ASCII file, or “all” in which case all trajectories are converted. It should be set to 0, if no conversion is desired.
resample.outrange	Logical indicating if values outside of the allowed gap range given by <code>gap.lim</code> should be resampled. If set to FALSE, such values are truncated instead.
verbose	Logical switching log messages on and off.
...	Further arguments passed to <code>e0.jmale.estimate</code> .

## Details

If no estimates are given, the function invokes an estimation by calling `e0.jmale.estimate`. Using those estimates, the male life expectancy is projected forward in time (as a function of a female-male gap), using the female predictions from `e0.pred`. The initial male data point is extracted from the male WPP dataset (`e0M`) and possibly partly replaced by any user-specified data given in `my.e0.file`.

The resulting trajectory files are stored in a subdirectory of the female prediction directory, called 'joint\_male'. Furthermore, an object of class `bayesLife.prediction` is created and added to `e0.pred` as a component called `joint.male`.

The predicted gaps can be viewed using the `e0.gap.plot` function.

## Value

Updated `e0.pred` object where a new component was added, called `joint.male`. It is also an object of class `bayesLife.prediction` and it contains results from this prediction.

e0.joint.plot

*Joint Posterior Distribution of Female and Male Life Expectancy*

---

### Description

The functions plot the joint posterior distribution of female and male life expectancy, modeled and predicted using the joint model described in Lalic (2011) and Raftery, Lalic & Gerland (2014). This can be done for one country (`e0.joint.plot`) or for all countries (`e0.joint.plot.all`).

### Usage

```
e0.joint.plot(e0.pred, country, pi = 95, years, nr.points = 500,
  obs.pch = 17, obs.cex=1, xlim = NULL,
  ylim = NULL, xlab = "Female life expectancy", ylab = "Male life expectancy",
  main = NULL, col = NULL, show.legend = TRUE, add = FALSE, ...)

e0.joint.plot.all(e0.pred, output.dir = file.path(getwd(), "e0joint"),
  output.type = "png", verbose = FALSE, ...)
```

### Arguments

<code>e0.pred</code>	Object of class <code>bayesLife.prediction</code> containing female projections.
<code>country</code>	Name or numerical code of a country. It can also be given as ISO-2 or ISO-3 characters.
<code>pi</code>	Probability interval. It can be a single number or an array.
<code>years</code>	Array of future years for which to plot the distribution.
<code>nr.points</code>	Number of points shown in the plot for each year.
<code>obs.pch, obs.cex</code>	Graphical parameters used for displaying observed data or data without variation.
<code>xlim, ylim, xlab, ylab, main</code>	Graphical parameters passed to the <code>plot</code> function.
<code>col</code>	Array of colors, one for each year.
<code>show.legend</code>	Logical controlling whether the legend should be drawn.
<code>add</code>	Logical controlling whether the distribution should be plotted into a new graphic device (FALSE) or into an existing device (TRUE).

output.dir	Directory into which resulting graphs are stored.
output.type	Type of the resulting files. It can be “png”, “pdf”, “jpeg”, “bmp”, “tiff”, or “postscript”.
verbose	Logical switching log messages on and off.
...	Additional graphical parameters passed to the <code>lines</code> function drawing ellipses. In addition, for <code>e0.joint.plot.all</code> , ... contains any of the arguments of <code>e0.joint.plot</code> .

### Examples

```
# See example for e0.jmale.predict
```

---

e0.map	<i>World Map of the Life Expectancy</i>
--------	---

---

### Description

Generates a world map of the life expectancy for given quantile and projection or estimation period, using different techniques: `e0.map` and `e0.map.all` use **rworldmap**, `e0.ggmap` uses **ggplot2**, and `e0.map.gvis` creates an interactive map via **GoogleVis**.

### Usage

```
e0.map(pred, ...)

e0.ggmap(pred, ...)

e0.map.all(pred, output.dir, output.type = "png",
  e0.range = NULL, nr.cats = 50, same.scale = TRUE,
  quantile = 0.5, file.prefix = "e0wrldmap_", ...)

get.e0.map.parameters(pred, e0.range = NULL,
  nr.cats = 50, same.scale = TRUE, quantile = 0.5, ...)

e0.map.gvis(pred, ...)
```

## Arguments

pred	Object of class <a href="#">bayesLife.prediction</a> .
output.dir	Directory into which resulting maps are stored.
output.type	Type of the resulting files. It can be “png”, “pdf”, “jpeg”, “bmp”, “tiff”, or “postscript”.
e0.range	Range of the life expectancy to be displayed. It is of the form $c(e0.min, e0.max)$ . By default, the whole range is considered. Note that countries with values outside of the given range will appear white.
nr.cats	Number of color categories.
same.scale	Logical controlling if maps for all years of this prediction object should be on the same color scale.
quantile	Quantile for which the map should be generated. It must be equal to one of the values in <code>dimnames(pred\$quantiles[[2]])</code> , i.e. 0, 0.025, 0.05, 0.1, 0.2, 0.25, 0.3, 0.4, 0.5, 0.6, 0.7, 0.75, 0.8, 0.9, 0.95, 0.975, 1. Value 0.5 corresponds to the median.
file.prefix	Prefix for file names.
...	In <code>e0.map</code> , ... are all arguments that can be passed to <a href="#">tfr.map</a> , such as <code>quantile</code> , <code>year</code> , <code>projection.index</code> , <code>par.name</code> , <code>adjusted</code> , <code>device</code> , <code>main</code> , <code>device.args</code> , and <code>data.args</code> . In <code>e0.map.gvis</code> , ... are all arguments that can be passed to <a href="#">tfr.map.gvis</a> . In <code>e0.ggmap</code> , ... are arguments that can be passed to <a href="#">tfr.ggmap</a> . In addition, functions that use the <b>rworldmap</b> package accept arguments passed to the <code>rworldmap::mapCountryData</code> function.

## Details

`e0.map` creates a single map for the given time period and quantile. `e0.map.all` generates a sequence of maps, namely one for each projection period. If the package **fields** is installed, a color bar legend at the bottom of the map is created.

Function `get.e0.map.parameters` can be used in combination with `e0.map`. (Note that `get.e0.map.parameters` is called from inside of `e0.map.all`.) It sets breakpoints for the color scheme using quantiles of a fitted gamma distribution.

Function `e0.ggmap` is similar to `e0.map`, but used the **ggplot2** package in combination with the `geom_sf` function.

Function `e0.map.gvis` creates an interactive map using the **googleVis** package and opens it in an internet browser. It also generates a table of the mapped values that can be sorted by columns interactively in the browser.

By default, both `e0.map`, `e0.ggmap` and `e0.map.gvis` produce maps of life expectancy. Alternatively, the functions can be used to plot country-specific MCMC parameters into a world map. They are given by the argument `par.name`. One can pass any value from `e0.parameter.names.cs.extended()`.

## Value

`get.e0.map.parameters` returns a list with elements:

pred	The object of class <a href="#">bayesLife.prediction</a> used in the function.
------	--

quantile	Value of the argument quantile.
catMethod	If the argument same.scale is TRUE, this element contains breakpoints for categorization. It is generated from a fitted gamma distribution. Otherwise, it is NULL.
numCats	Number of categories.
coulourPalette	Subset of the rainbow palette, starting from dark blue and ending at red.
...	Additional arguments passed to the function.

```

**Description**

These functions are to be used by expert analysts. They allow to change the projection medians either to specific values, including the WPP values, or shift the medians by a given constant or a factor.

**Usage**

```
e0.median.set(sim.dir, country, values, years = NULL, joint.male = FALSE, ...)
```

```
e0.median.shift(sim.dir, country, reset = FALSE, shift = 0,
  from = NULL, to = NULL, joint.male = FALSE, ...)
```

```
e0.median.adjust.jmale(sim.dir, countries, factors = c(1.2, 1.1),
  subdir = "predictions")
```

```
e0.median.reset(sim.dir, countries = NULL, joint.male = FALSE, ...)
```

```
e0.shift.prediction.to.wpp(sim.dir, joint.male = FALSE,
  subdir = "predictions", ...)
```

**Arguments**

sim.dir	Directory containing the prediction object.
country	Name or numerical code of a country.
countries	Vector of country names or codes. In the <code>e0.median.reset</code> function, if this argument is NULL (default), the reset is done for all countries.
values	Array of the new median values.
years	Numeric vector giving years which values correspond to. Ideally it should be of the same length as values. If it is NULL, values are set starting from the first prediction period. If values correspond to consecutive years, only the first year might be given here. A year $t$ represents a prediction period $[t_i, t_{i+1}]$ if $t_i < t \leq t_{i+1}$ .
joint.male	Logical. If TRUE, the function is applied to a male prediction that was generated using the joint female-male model implemented in the function <code>e0.jmale.predict</code> .
reset	Logical. If TRUE medians in a range of <code>from</code> and <code>to</code> are reset to their original values.
shift	Constant by which the medians should be offset. It is not used if <code>reset</code> is TRUE.
from	Year from which the offset/reset should start. By default, it starts at the first prediction period.
to	Year until which the offset/reset should be done. By default, it is set to the last prediction period.
factors	It should be a vector where each element corresponds to one time period. The adjustment of male medians is done as $e0m(t) = e0f(t) - \text{gap}(t) * \text{factor}(t)$ .
subdir	Subdirectory of <code>sim.dir</code> containing the predictions.
...	Additional arguments passed to the underlying adjustment function. For <code>e0.shift.prediction.to.wpp</code> it can be <code>stat</code> with values "median" (default) or "mean" to specify which statistics should be adjusted; <code>verbose</code> to show/hide the progress of the adjustment and <code>wpp.year</code> to adjust it to if it differs from the <code>wpp</code> year of the simulation. For the other functions it can be <code>subdir</code> to specify the location of the prediction.

## Details

The function `e0.median.set` can be used to set the medians of the given country to specific values. Function `e0.median.shift` can be used to offset the medians by a specific constant, or to reset the medians to their original BHM values. Function `e0.median.adjust.jmale` adjusts male medians using factors that can expand or shrink the female-male gap.

Function `e0.shift.prediction.to.wpp` shifts the projected medians or means (if `stat` is “mean”) so that they correspond to the values found in the `e0Fproj` (`joint.male = FALSE`) or `e0Mproj` (`joint.male = TRUE`) datasets of the **wpp** package that either corresponds to the package used for the simulation itself or is given by the `wpp.year` argument. If using **wpp2022** or higher, the dataset name is automatically adjusted depending if it is an annual or a 5-year simulation. Note that regardless if it is an adjustment of the median or mean, the corresponding offset is always converted to a shift of the median.

Function `e0.median.reset` resets medians of the given countries to the original values. By default it deletes adjustments for all countries.

In all cases, if a median is modified, the corresponding offset is stored in the prediction object (element `median.shift`). All functions write the updated prediction object back to disk. All functions in the package that use trajectories and trajectory statistics use the `median.shift` values to offset the results correspondingly, i.e. trajectories are shifted the same way as the medians.

## Value

All functions return an updated object of class `bayesLife.prediction`.

---

`e0.parameter.names`      *Accessing Parameter Names*

---

## Description

Functions for accessing names of the MCMC parameters, either country-independent or country-specific.

## Usage

```
e0.parameter.names(...)
e0.parameter.names.cs(...)
e0.parameter.names.extended(...)
e0.parameter.names.cs.extended(country.code = NULL, ...)
```

## Arguments

`country.code`      Country code. If it is given, the country-specific parameter names contain the suffix ‘`_cx`’ where `x` is the `country.code`.

`...`                  List of options containing elements `world.parameters` and `country.parameters`. If not given, they are obtained from the global environment, using `e0mcmc.options`.

**Value**

e0.parameter.names returns names of the world parameters.  
 e0.parameter.names.cs returns names of the country-specific parameters.  
 e0.parameter.names.extended returns names of all world parameters in their extended format. I.e. parameters 'Triangle' and 'lambda' have the suffix '\_1', '\_2', '\_3', and '\_4'.  
 e0.parameter.names.cs.extended returns names of all country-specific parameters in their extended format. I.e. parameters 'Triangle.c' and 'lambda.c' are in their extended format with the suffix '\_1', '\_2' and '\_3'.

**Author(s)**

Hana Sevcikova

**Examples**

```
e0.parameter.names()
e0.parameter.names.extended()
e0.parameter.names.cs()
e0.parameter.names.cs.extended()
```

---

e0.pardensity.plot      *Plotting MCMC Parameter Density*

---

**Description**

Functions for plotting density of the posterior distribution of the MCMC parameters.

**Usage**

```
e0.pardensity.plot(mcmc.list = NULL,
  sim.dir = file.path(getwd(), "bayesLife.output"),
  chain.ids = NULL, par.names = NULL,
  burnin = NULL, dev.ncol = 5, low.memory = TRUE, ...)

e0.pardensity.cs.plot(country, mcmc.list = NULL,
  sim.dir = file.path(getwd(), "bayesLife.output"),
  chain.ids = NULL, par.names = NULL,
  burnin = NULL, dev.ncol = 3, low.memory = TRUE, ...)
```

**Arguments**

country	Name or numerical code of a country.
mcmc.list	List of <code>bayesLife.mcmc</code> objects, or an object of class <code>bayesLife.mcmc.set</code> or of class <code>bayesLife.prediction</code> . If it is NULL, the parameter values are loaded from <code>sim.dir</code> .

sim.dir	Directory with the MCMC simulation results. It is only used if mcmc.list is NULL.
chain.ids	List of MCMC identifiers to be plotted. If it is NULL, all chains found in mcmc.list or sim.dir are plotted.
par.names	Names of parameters for which density should be plotted. By default all country-independent parameters are plotted if used within e0.pardensity.plot, or all country-specific parameters are plotted if used within e0.pardensity.cs.plot.
burnin	Number of iterations to be discarded from the beginning of each chain.
dev.ncol	Number of columns for the graphics device. If the number of parameters is smaller than dev.ncol, the number of columns is automatically decreased.
low.memory	Logical indicating if the processing should run in a memory-efficient mode.
...	Further arguments passed to the density function.

### Details

The functions plot the density of the posterior distribution either for country-independent parameters (e0.pardensity.plot) or for country-specific parameters (e0.pardensity.cs.plot), one graph per parameter. One can restrict it to specific chains by setting the chain.ids argument and to specific parameters by setting the par.names argument.

If mcmc.list is an object of class `bayesLife.prediction`, thinned traces are used instead of the full chains. In such a case, burnin and chain.ids cannot be modified - their value is set to the one used when the thinned traces were created, namely when running `e0.predict`.

e0.pardensity.cs.plot(country = "Ireland", sim.dir = sim.dir, burnin = 10)
```

---

e0.partraces.plot

*Plotting MCMC Parameter Traces*

---

### Description

Functions for plotting the MCMC parameter traces.

**Usage**

```
e0.partraces.plot(mcmc.list = NULL,
  sim.dir = file.path(getwd(), "bayesLife.output"),
  chain.ids = NULL, par.names = NULL,
  nr.points = NULL, dev.ncol = 5, low.memory = TRUE, ...)

e0.partraces.cs.plot(country, mcmc.list = NULL,
  sim.dir = file.path(getwd(), "bayesLife.output"),
  chain.ids = NULL, par.names = NULL,
  nr.points = NULL, dev.ncol = 3, low.memory = TRUE, ...)
```

**Arguments**

country	Name or numerical code of a country. It can also be given as ISO-2 or ISO-3 characters.
mcmc.list	List of bayesLife.mcmc objects, or an object of class bayesLife.mcmc.set or of class bayesLife.prediction. If it is NULL, the traces are loaded from sim.dir.
sim.dir	Directory with the MCMC simulation results. It is only used if mcmc.list is NULL.
chain.ids	List of MCMC identifiers to be plotted. If it is NULL, all chains found in mcmc.list or sim.dir are plotted.
par.names	Names of parameters for which traces should be plotted. By default all country-independent parameters are plotted if used within e0.partraces.plot, or country-specific parameters are plotted if used within e0.partraces.cs.plot.
nr.points	Number of points to be plotted. If NULL, all (stored) points are plotted, otherwise the traces are thinned evenly.
dev.ncol	Number of column for the graphics device. If the number of parameters is smaller than dev.ncol, the number of columns is automatically decreased.
low.memory	Logical indicating if the processing should run in a low-memory mode. If it is FALSE, traces of all available parameters are loaded into memory. Otherwise, parameters are loaded as they are needed and are not kept in the memory.
...	Additional graphical arguments. It can also contain the arguments burnin or thin.

**Details**

The functions plot MCMC traces either for country-independent parameters (`e0.partraces.plot`) or for country-specific parameters (`e0.partraces.cs.plot`), one graph per parameter. One can restrict it to specific chains by setting the `chain.ids` argument, and to specific parameters by setting the `par.names` argument.

---

e0.predict

*Generating Posterior Trajectories of the Life Expectancy*

---

**Description**

Using the posterior parameter samples simulated by [run.e0.mcmc](#) the function generates posterior trajectories for the life expectancy for all countries of the world.

**Usage**

```
e0.predict(mcmc.set = NULL, end.year = 2100,
  sim.dir = file.path(getwd(), "bayesLife.output"), replace.output = FALSE,
  predict.jmale = TRUE, nr.traj = NULL, thin = NULL, burnin = 10000,
  use.diagnostics = FALSE, save.as.ascii = 0, start.year = NULL,
  output.dir = NULL, subdir = "predictions", low.memory = TRUE,
  ignore.last.observed = FALSE, seed = NULL, verbose = TRUE, ...)
```

**Arguments**

mcmc.set	Object of class <a href="#">bayesLife.mcmc.set</a> . If it is NULL, the object is loaded from the directory given by <code>sim.dir</code> .
end.year	End year of the prediction.
sim.dir	Directory with the MCMC simulation results. It should equal to the <code>output.dir</code> argument in <a href="#">run.e0.mcmc</a> .
replace.output	Logical. If TRUE, existing predictions in <code>output.dir</code> will be replaced by results of this run.
predict.jmale	Logical controlling if a joint female-male prediction should be performed. This is done only if the underlying mcmcs in <code>sim.dir</code> correspond to a female simulation. In such a case the <a href="#">e0.jmale.predict</a> is invoked. Arguments to this function can be passed in ....
nr.traj	Number of trajectories to be generated. If NULL, the argument <code>thin</code> is taken to determine the number of trajectories. If both are NULL, the number of trajectories corresponds to the minimum of the size of the parameter sample and 2000.
thin	Thinning interval used for determining the number of trajectories. Only relevant, if <code>nr.traj</code> is NULL.
burnin	Number of iterations to be discarded from the beginning of the parameter traces.

<code>use.diagnostics</code>	Logical determining if an existing convergence diagnostics should be used for choosing the values of <code>thin</code> and <code>burnin</code> . In such a case, arguments <code>nr.traj</code> , <code>thin</code> and <code>burnin</code> are ignored. The ‘best’ values are chosen from results of running the <code>e0.diagnose</code> function. Only diagnostics can be used that suggest a convergence of the underlying MCMCs. If there are more than one such objects, the one is chosen whose recommendation for the number of trajectories is larger and closest to 2000.
<code>save.as.ascii</code>	Either a number determining how many trajectories should be converted into an ASCII file, or “all” in which case all trajectories are converted. It should be set to 0, if no conversion is desired (default).
<code>start.year</code>	This argument should be only used if the start year of the prediction is before or at the present year of the MCMC run (see Details below). By default the prediction starts in the next time period after the present year (passed to <code>run.e0.mcmc</code> ).
<code>output.dir</code>	Directory into which the resulting prediction object and the trajectories are stored. If it is NULL, it is set to either <code>sim.dir</code> , or to <code>output.dir</code> of <code>mcmc.set\$meta</code> if <code>mcmc.set</code> is given.
<code>subdir</code>	Subdirectory of <code>output.dir</code> to store the predictions. It is defined relative to <code>output.dir</code> and can only have one level.
<code>low.memory</code>	Logical indicating if the prediction should run in a low-memory mode. If it is FALSE, the whole traces of all parameters, including the burnin, are loaded into memory. Otherwise, burnins are discarded and parameters are loaded as they are needed and are not kept in the memory.
<code>ignore.last.observed</code>	Logical. By default, the prediction (or imputation) for each country starts one time period after the last observed data point for that country defined by the “last.observed” column in the data. If this argument is set to TRUE, the prediction ignores that “last.observed” value and starts at the last data point found in the data. This allows to exclude some time periods from the estimation, but include them in the prediction.
<code>seed</code>	Seed of the random number generator. If NULL no seed is set. It can be used to generate reproducible projections.
<code>verbose</code>	Logical switching log messages on and off.
<code>...</code>	Additional arguments passed to the <code>e0.jmale.predict</code> function.

## Details

The trajectories are generated using the double logistic function (Chunn et al. 2013). Parameter samples simulated via `run.e0.mcmc` are used from all chains, from which the given burnin was discarded. They are evenly thinned to match `nr.traj` or using the `thin` argument. Such thinned parameter traces, collapsed into one chain, if they do not already exist, are stored on disk into the sub-directory ‘`thinned_mcmc_t_b`’ where  $t$  is the value of `thin` and  $b$  the value of `burnin` (see `create.thinned.e0.mcmc`).

The projection is run for all missing values before the present year, if any. Medians over the trajectories are used as imputed values and the trajectories are discarded. The process then continues by projecting the future values where all generated trajectories are kept.

A special case is when the argument `start.year` is given that is smaller or equal the present year. In such a case, imputed missing values before present year are treated as ordinary predictions (trajectories are kept). All historical data between start year and present year are used as projections.

The resulting prediction object is saved into `{output.dir}/{subdir}`. Trajectories for all countries are saved into the same directory in a binary format, one file per country. At the end of the projection, if `save.as.ascii` is larger than 0, the function converts the given number of trajectories into a CSV file of a UN-specific format. They are selected by equal spacing (see function [convert.e0.trajectories](#) for more details on the conversion). In addition, two summary files are created: one in a user-friendly format, the other using a UN-specific coding of the variants and time (see [write.e0.projection.summary](#) for more details).

### Value

Object of class `bayesLife.prediction` which is a list containing components:

<code>quantiles</code>	A $n \times q \times p$ array of quantile values computed on the trajectories. $n$ is the number of countries, $q$ is the number of quantiles and $p$ is the number of projections. Which quantiles are to be computed is determined by the global option <code>e0pred.options("quantiles")</code> .
<code>traj.mean.sd</code>	A $n \times 2 \times p$ array holding the mean of all trajectories in the first column and the standard deviation in the second column. $n$ and $p$ are the number of countries and number of projections, respectively.
<code>nr.traj</code>	Number of trajectories.
<code>e0.matrix.reconstructed</code>	Matrix containing imputed e0 values on spots where the original e0 matrix has missing values, i.e. between the last observed data point and the present year.
<code>output.directory</code>	Directory where trajectories corresponding to this prediction are stored.
<code>nr.projections</code>	Number of projections.
<code>burnin</code>	Burnin used for this prediction.
<code>end.year</code>	The end year of this prediction.
<code>start.year</code>	The <code>start.year</code> input argument.
<code>mcmc.set</code>	Object of class <code>bayesLife.mcmc.set</code> used for this prediction, i.e. the burned, thinned, and collapsed MCMC chain.
<code>joint.male</code>	If <code>e0.jmale.predict</code> was invoked, this is an object of class <code>bayesLife.prediction</code> containing male projections. In addition to the components above, it contains elements <code>fit</code> (estimation results from <code>e0.jmale.estimate</code> ) and <code>meta.changes</code> (components of <code>bayesLife.mcmc.meta</code> that differ from the female meta component).

e0.predict.extra	<i>Generating Posterior Trajectories of the Life Expectancy for Specific Countries or Regions</i>
------------------	---

---

## Description

Using the posterior parameter samples the function generates posterior trajectories of the life expectancy for given countries or regions. It is intended to be used after running [run.e0.mcmc.extra](#), but it can be also used for purposes of testing specific settings on one or a few countries.

## Usage

```
e0.predict.extra(sim.dir = file.path(getwd(), 'bayesLife.output'),
  prediction.dir = sim.dir, subdir = "predictions", countries = NULL,
  save.as.ascii = 1000, verbose = TRUE, ...)
```

## Arguments

sim.dir	Directory with the MCMC simulation results.
prediction.dir	Directory where the prediction object and the trajectories are stored.
subdir	Subdirectory of prediction.dir containing the predictions.
countries	Vector of country codes for which the prediction should be made. If it is NULL, the prediction is run for all countries that are included in the MCMC object but for which no prediction was generated.

save.as.ascii Either a number determining how many trajectories should be converted into an ascii file, or “all” in which case all trajectories are converted. It should be set to 0, if no conversions is desired. Note that the conversion is done on all countries.

verbose Logical switching log messages on and off.

... Additional arguments passed to a joint female-male prediction.

### Details

In order to use this function, a prediction object must exist, i.e. the function `e0.predict` must have been processed prior to using this function.

Trajectories for given countries or regions are generated and stored in binary format along with other countries (in `prediction.dir`). The existing prediction object is updated and stored in the same directory. If `save.as.ascii` is larger than zero, trajectories of ALL countries are converted to an ascii format.

If the prediction object contains joint male projections, these are also created for the given countries.

### Value

Updated object of class `bayesLife.prediction`.

<code>e0.predict.subnat</code>	<i>Generating Posterior Trajectories of Subnational Life Expectancy at Birth</i>
--------------------------------	--

---

### Description

Generates posterior trajectories of the life expectancy at birth (e0) for subregions of given countries, for female and male.

### Usage

```
e0.predict.subnat(countries, my.e0.file,
  sim.dir = file.path(getwd(), "bayesLife.output"),
  method = c("ar1", "shift", "scale"),
  predict.jmale = FALSE, my.e0M.file = NULL,
  end.year = 2100, start.year = NULL, subdir = "predictions",
  output.dir = NULL, annual = NULL, nr.traj = NULL, seed = NULL,
  ar.pars = NULL, save.as.ascii = 0, verbose = TRUE,
  jmale.estimates = NULL, ...)
```

```
e0.jmale.predict.subnat(e0.pred, estimates = NULL,
  gap.lim = c(0,18), max.e0.eq1.pred = 86, my.e0.file = NULL,
  save.as.ascii = 0, verbose = TRUE)
```

```
subnat.gap.estimates(annual = FALSE)
```

## Arguments

countries	Vector of numerical country codes or country names.
my.e0.file	Tab-separated ASCII file containing the subnational e0 data. In <code>e0.predict.subnat</code> , if female and male e0 are projected jointly (i.e. <code>predict.jmale</code> is TRUE), this file should contain the female e0. In <code>e0.jmale.predict.subnat</code> , this file should contain the male e0. See Details for more information on its format.
sim.dir	Simulation directory with the national projections generated using <code>e0.predict</code> .
method	Method to use for the projections, see the reference paper.
predict.jmale	Logical determining if male projections should be generated as well. If TRUE, the argument <code>my.e0M.file</code> must be given.
my.e0M.file	Tab-separated ASCII file containing the subnational male e0 data.
end.year	End year of the projections.
start.year	Start year of the projections. By default, projections start at the same time point as the national projections.
subdir	Subdirectory of <code>sim.dir</code> containing the national predictions.
output.dir	Directory into which the resulting prediction objects and the trajectories are stored. See below for details.
annual	Logical indicating if the subnational projection should be on an annual scale or a 5-year scale. By default, the scale is matched to the national simulation given by <code>sim.dir</code> . If given, the scale must match to the scale of the subnational data provided in <code>my.e0.file</code> . If the subnational and national scales are not the same, the national trajectories are either interpolated (if <code>annual = TRUE</code> and the national simulation is not annual) or averaged to 5-year values (if <code>annual = FALSE</code> and the national simulation is annual).
nr.traj	Number of trajectories to be generated. If NULL, the number of trajectories in the national projections is used.
seed	Seed of the random number generator. If NULL no seed is set. It can be used to generate reproducible projections.
ar.pars	Named vector containing the parameter estimates for the AR(1) method (i.e. if <code>method = "ar1"</code> , default). If given, it must have elements called <code>rho</code> , <code>U</code> , <code>a</code> and <code>b</code> . See the reference paper for details on the estimation. By default for a 5-year simulation, <code>c(rho = 0.95, U = 82.5, a = 0.0482, b = -0.0154)</code> is used. For an annual simulation these default parameters are scaled to <code>c(rho = 0.9898, U = 82.5, a = 0.01, b = -0.0032)</code> , see details below.
save.as.ascii	Either a number determining how many trajectories should be converted into an ASCII file, or "all" in which case all trajectories are converted. By default no conversion is performed.

verbose	Logical switching log messages on and off.
jmale.estimate, estimates	List with estimates for the female-male gap model. The default values are retrieved using the function <code>subnat.gap.estimate()</code> .
...	Additional arguments passed to <code>e0.jmale.predict.subnat</code> , which are <code>gap.lim</code> and <code>max.e0.eq1.pred</code> .
e0.pred	Object of class <code>bayesLife.prediction</code> . It should be one element of the list returned by <code>e0.predict.subnat</code> corresponding to one country.
gap.lim, max.e0.eq1.pred	The same meaning as in <code>e0.jmale.predict</code> .

## Details

The `e0.predict.subnat` function implements the methodology described in Sevcikova and Raftery (2021). Given a set of national bayesLife projections, it applies one of the methods (AR(1), Shift or Scale) to each national trajectory and each subregion of given countries which yields subnational e0 projections.

The file on subnational data passed into `my.e0.file` and `my.e0M.file` has to have a column “country\_code” with numerical values corresponding to countries given in the argument `countries`, and column “reg\_code” giving the numerical identifier of each subregion. Column “name” should be used for subregion name, and column “country\_name” for country name. An optional column “include\_code” can be used to eliminate entries from processing. Entries with values of 1 or 2 will be included, all others will be ignored. Column “last.observed” can be used to define which time period contains the last observed data point (given as integer, e.g. year in the middle of the time period). Remaining columns define the time periods, e.g. “2000-2005”, “2005-2010” for a 5-year simulation, or “2020”, “2021” for an annual simulation. The package contains an example of such dataset, see Example below.

The default AR(1) parameters for the “ar1” method were designed for a 5-year simulation, see Sevcikova & Raftery (2021) for more detail. These are  $\rho = 0.95$ ,  $U = 82.5$ ,  $a = 0.0482$ ,  $b = -0.0154$ . If an annual AR(1) process is desired, we use the following conversion for the autoregressive parameter  $\rho$  and the  $a$  and  $b$  parameters:  $\rho^* = \rho^{(1/5)}$ ,  $a^* = a * \sqrt{((1 - \rho^{(2/5)}) / (1 - \rho^2))}$ ,  $b^* = b * \sqrt{((1 - \rho^{(2/5)}) / (1 - \rho^2))}$ . The  $U$  parameter stays the same for both processes. Thus, the annual parameters are `c(rho = 0.9898, U = 82.5, a = 0.01, b = -0.0032)`. Note that if the `ar.pars` argument is specified by the user, it is assumed that the parameters have been scaled appropriately and thus, no conversion takes place.

Argument `output.dir` gives a location on disk where results of the function should be stored. If it is NULL (default), results are stored in the same directory as the national projections. In both cases a subdirectory called “subnat\_method” is created in which each country has its own subfolder with the country code in its name. Each such subfolder contains the same type of outputs as in the national case generated using `e0.predict`, most importantly a directory “predictions” with trajectories for each region.

If the argument `predict.jmale` is TRUE, the `e0.predict.subnat` invokes the `e0.jmale.predict.subnat` function for each country. However, one can call the `e0.jmale.predict.subnat` function explicitly. It applies the female-male gap model to regions of one country. See `e0.jmale.predict` for more detail on the model. The default covariates of the model are not estimated on the fly. They were estimated externally using subnational data for about 30 countries and can be viewed using

subnat.gap.estimates(), either for estimates derived from 5-year data (default) or annual data (annual = TRUE).

### Value

Function `e0.predict.subnat` returns a list of objects of class `bayesLife.prediction`. The name of each element includes its country code. Not all elements of the class `bayesLife.prediction` are available. For example, no `mcmc.set` is attached to these objects. Thus, not all functions that work with `bayesLife.prediction` can be applied to these results.

Function `e0.jmale.predict.subnat` returns an object of class `bayesLife.prediction` which updates the input `e0.pred` object by adding a new component called `joint.male`. This component is also an object of class `bayesLife.prediction` and it contains results of the male projections.

### Note

Even though the resulting object contains subnational results, the names of its elements are the same as in the national case. This allows to apply the same functions on both objects (subnational and national). However, it means that sometimes the meaning of the elements or function arguments does not match the subnational context. For example, various functions expect the argument `country`. When a subnational object is passed to such a function, `country` means a subregion.

---

e0.raftery.diag

*Raftery Diagnostics for Parameters of the Life Expectancy*

---

## Description

The function computes the Raftery diagnostics for each parameter in the same way as [tfr.raftery.diag](#) of the **bayesTFR** package.

## Usage

```

e0.raftery.diag(mcmc = NULL, sim.dir = file.path(getwd(), "bayesLife.output"),
  burnin = 0, country = NULL, par.names = NA, par.names.cs = NA,
  country.sampling.prop = 1, verbose = TRUE, ...)

```

## Arguments

mcmc                    A [bayesLife.mcmc](#) or [bayesLife.mcmc.set](#) object.

sim.dir	Directory with the MCMC simulation results. Only used if mcmc is NULL.
burnin	Burnin.
country	Name or code of a country. If it is given, only country-specific parameters parameters of that country are considered.
par.names	Names of country-independent parameters for which the Raftery diagnostics should be computed. By default all parameters are used. If it is NULL, no country-independent parameters are used.
par.names.cs	Names of country-specific parameters for which the Raftery diagnostics should be computed. By default all parameters are used. If it is NULL, no country-specific parameters are used.
country.sampling.prop	Proportion of countries that are included in the diagnostics. It should be between 0 and 1. If it is smaller than 1, the countries are randomly sampled. It is only relevant if par.names.cs is not NULL.
verbose	Logical switching log messages on and off.
...	Additional arguments passed to the <a href="#">e0.coda.list.mcmc</a> function.

### Details

See [tfr.raftery.diag](#) for details. This function is called from [e0.diagnose](#).

### Author(s)

e0.trajectories.plot *Posterior Distribution of Trajectories of Life Expectancy*

---

### Description

The functions plot/tabulate the posterior distribution of trajectories of the life expectancy for a given country, or for all countries, including their median and given probability intervals.

### Usage

```
e0.trajectories.plot(e0.pred, country, pi = c(80, 95), both.sexes = FALSE,
  nr.traj = NULL, adjusted.only = TRUE, typical.trajectory = FALSE,
  traj.index = NULL, show.mean = FALSE, show.median = TRUE,
  xlim = NULL, ylim = NULL, type = "b",
  xlab = "Year", ylab = "Life expectancy at birth", main = NULL,
  lwd = c(2, 2, 2, 2, 1), col = c('black', 'green', 'red', 'red', '#00000020'),
  col2 = c('gray39', 'greenyellow', 'hotpink', 'hotpink', '#00000020'),
```

```

pch = c(1, 2), show.legend = TRUE, add = FALSE, ...)

e0.trajectories.plot.all(e0.pred,
  output.dir = file.path(getwd(), 'e0trajectories'),
  output.type = "png", verbose = FALSE, ...)

e0.trajectories.table(e0.pred, country, pi = c(80, 95),
  both.sexes = FALSE, ...)

```

## Arguments

e0.pred	Object of class <a href="#">bayesLife.prediction</a> .
country	Name or numerical code of a country. It can also be given as ISO-2 or ISO-3 characters.
pi	Probability interval. It can be a single number or an array. If both.sexes is TRUE the default is 95.
both.sexes	Logical or the character "A". If TRUE the distribution of both sexes is plotted into one graphics (or tabulated), provided the e0.pred is a female prediction and contains a joint male prediction as a result of running the function <a href="#">e0.jmale.predict</a> . For "A" it plots/tabulates the distribution of the average life expectancy over both sexes.
nr.traj	Number of trajectories to be plotted. If NULL, all trajectories are plotted, otherwise they are thinned evenly. If both.sexes is TRUE the default is zero.
adjusted.only	Logical. By default, if the projection median is adjusted using e.g. <a href="#">e0.median.set</a> , the function plots the adjusted median. If adjusted.only=FALSE the original (non-adjusted) median is plotted as well.
typical.trajectory	Logical. If TRUE one trajectory is shown for which the median absolute deviation from the median e0 projection is the median among all the trajectories.
traj.index	Vector of trajectory indices to show. If not given, the trajectories are selected using equidistant spacing.
show.mean, show.median	Logical indicating if the mean or/and the median of the distribution should be shown.
xlim, ylim, type, xlab, ylab, main	Graphical parameters passed to the plot function.
lwd, col, col2	Vector of five elements giving the line width and color for: 1. observed data, 2. imputed missing data, 3. median, 4. quantiles, 5. trajectories. col2 is only used if both.sexes is TRUE. In such a case, col2 is used for female lines and col is used for male lines, which in this case defaults to c('black', 'green', 'darkgreen', 'darkgreen', 'gray').
pch	Vector of two elements specifying plotting symbols for the observed and imputed data, respectively. It is not used if type is not one of "b", "p" or "o".
show.legend	Logical controlling whether the legend should be drawn.

add	Logical controlling whether the trajectories should be plotted into a new graphic device (FALSE) or into an existing device (TRUE). One can use this argument to plot trajectories from multiple countries into one graphics.
...	Additional graphical parameters. In addition, for <code>e0.trajectories.plot.all</code> , ... contains any of the arguments of <code>e0.trajectories.plot</code> , and for <code>e0.trajectories.table</code> , ... contains the <code>pi</code> and <code>country</code> arguments.
output.dir	Directory into which resulting graphs are stored.
output.type	Type of the resulting files. It can be "png", "pdf", "jpeg", "bmp", "tiff", or "postscript".
verbose	Logical switching log messages on and off.

### Details

`e0.trajectories.plot` plots posterior distribution of trajectories of life expectancy for a given country. `e0.trajectories.table` gives the same output in a tabular format.

`e0.trajectories.plot.all` creates a set of such graphs (one per country) that are stored in `output.dir`.

The median and given probability intervals are computed using all available trajectories. Thus, `nr.traj` does not influence those values - it is used only to control the number of trajectories plotted.

---

eOptions

*Global options*

---

### Description

Setting, retrieving and updating global options.

### Usage

```
using.bayesLife()
eOptions()
eMcmc.options(..., annual = FALSE)
ePred.options(...)

eMcmc.dlpriors.options(prior.choice = "B", annual = FALSE,
  un.constraints = FALSE)

get.Dlpriors(prior.choice = NULL, annual = FALSE)

data(Dlpriors)
```

### Arguments

...	Arguments in tag = value form, or names of options to retrieve.
annual	Logical indicating if the options are for an annual simulation (TRUE) or a 5-year simulation(FALSE).
prior.choice	A character indicating for which combination of the upper bound on the $z$ parameter and the upper bound of <code>sumTriangle.lim</code> priors for $a$ , $\delta$ and $\tau$ should be used. Choices are "A" (0.653, 83), "B" (0.653, 86; default), "C" (1.150, 83), "D" (1.150, 86). See Details for more information. Use <code>get.Dlpriors()</code> to view the priors. If this argument is NULL no update/choice is taken.
un.constraints	Logical indicating if constraints on the lower bounds of the <code>Triangle</code> parameter posed by the UN in WPP 2022 should be used.

### Details

Function `using.bayesLife` sets all global options to their default values. Function `eOptions` is used to get all options as a named list.

The global options are divided into three main categories, namely options used for MCMC estimations in a 5-year simulation, in a 1-year simulation, and options used for predictions. To set or retrieve options of the first two categories, use `eMcmc.options` and use the argument `annual` to distinguish between them (see section MCMC Options below), while the third category is controlled by `ePred.options` (see section Prediction Options below).

Many options are in the form of a list and it is possible to overwrite only single elements of the list. However, if an option is a vector, all elements of the vector have to be defined when updating (see Example).

The dataset `DLpriors` contains four sets of parameters `a`, `delta` and `tau` (see section MCMC Options below) estimated for different combinations of the upper limit on the `z` parameter (i.e. maximum 5-year increase of `e0`; column “Uz”) and the upper bound of the sum of  $\Delta_i$  (column “Sa”; set in the `sumTriangle.lim` option which is interpreted as the value of `e0` for which the transition is completed; see below for more detail). A `get.DLpriors()` call retrieves all available combinations. Function `e0mcmc.dlpriors.options` can be used to change the default option B (i.e. the upper limit on `z` being 0.653 and the transition being completed at `e0` of 86). Use the column “option” from `DLpriors` to select the desired combination. In addition, setting the argument `un.constraints` to `TRUE` will set the lower limit on the  $\Delta_i$  parameters (`Triangle`, `Triangle.c`) to the same values as the UN used for WPP 2022. Note that the `DLpriors` dataset corresponds to parameter values designed for a 5-year simulation. Use `get.DLprior(annual = TRUE)` to see the equivalents for an annual simulation where various values are divided by five.

## Value

`e0options` returns a list of all global options.

`e0mcmc.options`, when called with no argument other than `annual`, it returns a list of options related to the MCMC estimation. The `annual` argument determines if the values correspond to an annual or 5-year simulation.

`e0pred.options`, when called with no argument, it returns a list of options related to the prediction.

For both, `e0mcmc.options` and `e0pred.options`, when a specific option is queried, it returns the value of that option. When an option is set, a list of the previous values of all MCMC/prediction options is returned invisibly.

`get.DLpriors` returns the content of the `DLpriors` dataset.

`e0mcmc.dlpriors.options` overwrites various values and like `e0mcmc.options`, it returns a list of the previous values of all MCMC options invisibly.

## MCMC Options

**a** vector of the  $a_1, \dots, a_6$  parameters, which are the prior means of the world-level parameters ( $\Delta_1, \dots, \Delta_4, k, z$ ).

**delta** vector of the  $\delta_1, \dots, \delta_6$  parameters, which are the prior standard deviations of the world-level parameters ( $\Delta_1, \dots, \Delta_4, k, z$ ).

**tau** vector of the  $\tau_1, \dots, \tau_6$  parameters, which is the square root rate of the prior Gamma distribution of the world-level parameters ( $\lambda_1, \dots, \lambda_4, \lambda_k, \lambda_z$ ).

**Triangle** list with elements:

**ini** list with elements:

**T1, T2, T3, T4** initial values for  $\Delta_1, \dots, \Delta_4$ . If not `NULL`, then each element should be of the same length as the number of MCMC chains. If it is `NULL`, the initial values

are equally spaced between `ini.low` and `ini.up` for the respective parameter. By default in the estimation, if there is just one chain, the initial value is the middle point of the interval.

**ini.low, ini.up** vectors of length four. They are the lower and upper bounds for initial values of  $\Delta_1, \dots, \Delta_4$ . An  $i$ -th item is only used if `ini$Ti` is NULL.

**prior.low, prior.up** vectors of length four. They are the lower and upper bounds for the prior (truncated normal) distribution of  $\Delta_1, \dots, \Delta_4$ .

**slice.width** vector of length four defining the slice width for MCMC slice sampling for the four parameters,  $\Delta_1, \dots, \Delta_4$ .

**k, z** lists with elements:

**ini** vector of initial values for  $k$  ( $z$ ). Its length (if not NULL) should correspond to the number of MCMC chains. By default, the initial values are equally spaced between `ini.low` and `ini.up`. In case of one chain, the initial value is by default the middle point of the interval.

**ini.low, ini.up** single value giving the lower and upper bounds for initial values of  $k$  ( $z$ ). It is only used if `ini` is NULL. Regarding defaults for the  $z$  parameter, see Note below.

**prior.low, prior.up** single value giving the lower and upper bounds for the prior (truncated normal) distribution of  $k$  ( $z$ ). Regarding defaults for the  $z$  parameter, see Note below.

**slice.width** single value giving the slice width for MCMC slice sampling of the  $z$  parameter (not available for  $k$ ).

**lambda** list with elements:

**ini** list with elements:

**T1, T2, T3, T4** initial values for  $\lambda_1, \dots, \lambda_4$ . Each element should be of the same length as the number of MCMC chains. If it is NULL, the initial values are equally spaced between `ini.low` and `ini.up` of the respective parameter. By default, if there is just one chain, the value is the middle point of the interval.

**ini.low, ini.up** vectors of length four. They are the lower and upper bounds for initial values of  $\lambda_1, \dots, \lambda_4$ . An  $i$ -th item is only used if `ini$Ti` is NULL.

**slice.width** vector of length four defining the slice width for MCMC slice sampling for the four parameters,  $\lambda_1, \dots, \lambda_4$ .

**lambda.k, lambda.z** lists with elements:

**ini** vector of initial values for  $\lambda_k$  ( $\lambda_z$ ). Its length (if not NULL) should correspond to the number of MCMC chains. By default, the initial values are equally spaced between `ini.low` and `ini.up`. In case of one chain, the initial value is by default the middle point of the interval.

**ini.low, ini.up** single value giving the lower and upper bounds for initial values of  $\lambda_k$  ( $\lambda_z$ ). It is only used if `ini` is NULL.

**slice.width** single value giving the slice width for MCMC slice sampling of the  $\lambda_z$  parameter (not available for  $\lambda_k$ ).

**omega** list with elements:

**ini** vector of initial values for  $\omega$ . Its length (if not NULL) should correspond to the number of MCMC chains. By default, the initial values are equally spaced between `ini.low` and `ini.up`. In case of one chain, the initial value is by default the middle point of the interval.

**ini.low, ini.up** single value giving the lower and upper bounds for initial values of  $\omega$ . It is only used if `ini` is NULL.

**Triangle.c** list with elements:

**ini.norm** list with elements:

**mean, sd** vectors of size four. They correspond to the means and standard deviations, respectively, for the initial values of the country-specific parameters  $\Delta_1^c, \dots, \Delta_4^c$  which are drawn from a truncated normal distribution with bounds defined by `prior.low` and `prior.up`.

**prior.low, prior.up** vectors of length four. They are the lower and upper bounds for the prior (truncated normal) distribution of country-specific  $\Delta_1^c, \dots, \Delta_4^c$ .

**slice.width** vector of length four defining the slice width for MCMC slice sampling of the country-specific  $\Delta_1^c, \dots, \Delta_4^c$ .

**k.c, z.c** list with elements:

**ini.norm** named vector of length two, called “mean” and “sd”. The elements correspond to the means and standard deviations, respectively, for the initial values of the country-specific parameters  $k^c (z^c)$  which are drawn from a normal distribution truncated between `prior.low` and `prior.up`.

**prior.low, prior.up** single values giving the lower and upper bounds for the prior (truncated normal) distribution of country-specific  $k^c (z^c)$ . Regarding defaults for  $z^c$ , see Note below.

**slice.width** single value giving the slice width for MCMC slice sampling of the  $k^c (z^c)$  parameter.

**nu** the shape parameter of the Gamma distributions of all  $\lambda$  parameters is `nu/2`.

**dl.p1, dl.p2** values of the parameters  $p_1$  and  $p_2$  of the double logistic function.

**sumTriangle.lim** lower and upper limits for the sum of the  $\Delta_i$  parameters. MCMC proposals that are outside of this limit are rejected. It is applied to both, the world parameters as well as the country specific parameters. The sum of  $\Delta_i$  can be interpreted as the level of `e0` at which the transition is completed and is followed by an `e0` increase with a constant rate `z`.

**world.parameters** named vector where names are the world parameters and values are the number of sub-parameters. For example,  $\Delta$  has 4 sub-parameters, while  $k$  and  $z$  are both just one parameter.

**country.parameters** named vector where names are the country-specific parameters and values are the number of sub-parameters.

**outliers** ranges for determining outliers in the historical data. If `outliers=c(x, y)` then any increase in life expectancy smaller than `x` or larger than `y` is considered as an outlier and removed from the estimation.

**buffer.size** buffer size (in number of [thinned] iterations) for keeping data in the memory. The smaller the `buffer.size` the more often will the process access the hard disk and thus, the slower the run. On the other hand, the smaller the `buffer.size` the less data will be lost in case of failure.

**auto.conf** list containing a configuration for an ‘automatic’ run. All items in this list must be integer values. The option is only used if the argument `iter` in `run.e0.mcmc` is set to ‘auto’ (see description of argument `iter` in `run.e0.mcmc`). The list contains the following elements:

**iter** gives the number of iterations in the first chunk of the MCMC simulation.

**iter.incr** gives the number of iterations in the following chunks.

**nr.chains** gives the number of chains in all chunks of the MCMC simulation.

**thin, burnin** used in the convergence diagnostics following each chunk.

**max.loops** controls the maximum number of chunks.

**country.overwrites** This option allows to overwrite some of the prior parameters for specific countries. If it is not NULL it should be a data frame with an obligatory column 'country\_code'. Each row then corresponds to one country. Other columns can be 'k.c.prior.low', 'k.c.prior.up', 'z.c.prior.low', 'z.c.prior.up', 'Triangle\_x.c.prior.low' and 'Triangle\_x.c.prior.up' where  $x$  can be an integer from 1 to 4.

### Note

Parameter  $z$  determines the asymptote in gains in life expectancy. The following text gives an explanation for the choice of upper limits on  $z$ -related parameters:

The pace of improvement and the asymptotic limit in future gains in female life expectancy vary for each projected trajectory, but ultimately is informed and constrained by the finding that the rate of increase of maximum female life expectancy over the past 150 year has been highly linear (2a, 2b) (i.e., about 2.4 years per decade), albeit at slightly lower pace once the leading countries started to exceed 75 years of female life expectancy at birth in the 1960s (3) (about 2.26 years of gains per decade). By assuming that the asymptotic average rate of increase in life expectancy is nonnegative, life expectancy is assumed to continually increase (on average), and no limit is imposed to life expectancy in the foreseeable future. The increase in maximum female life span among countries with highest life expectancy and reliable data on very old age provide further guidance on future rate of progress which has also been increasingly linear at least since the 1970s (4a-4c) (about 1.25 years per decade for countries like Sweden and Norway), and is used to inform the asymptotic average rate of increase in female life expectancy used in the 2012 WPP Revision. To set the posterior median to an annual gain of 0.125 year (or 5-year gain of 0.625 in this context) the upper bound value of 0.653 is used for the world prior ( $z$ ) and country-specific prior ( $z_c$ ) as default values in the estimation of the double-logistic parameters.

---

get.e0.convergence      *Accessing a Convergence Object*

---

### Description

The functions load objects of class `bayesLife.convergence` from disk that were created using the function `e0.diagnose`.

### Usage

```
get.e0.convergence(sim.dir = file.path(getwd(), "bayesLife.output"),
  thin = 225, burnin = 10000)

get.e0.convergence.all(sim.dir = file.path(getwd(), "bayesLife.output"))
```

### Arguments

sim.dir	Simulation directory used for computing the diagnostics.
thin	Thinning interval used with this diagnostics.
burnin	Burnin used for computing the diagnostics.

### Details

Function `get.e0.convergence` loads an object of class `bayesLife.convergence` for the specific `thin` and `burnin`. Function `get.e0.convergence.all` loads all `bayesLife.convergence` objects available in `sim.dir`.

### Value

`get.e0.convergence` returns an object of class `bayesLife.convergence`;  
`get.e0.convergence.all` returns a list of objects of class `bayesLife.convergence`.

### Author(s)

Hana Sevcikova

### See Also

---

get.e0.mcmc

*Accessing MCMC Results*

---

### Description

The function `get.e0.mcmc` retrieves results of an MCMC simulation and creates an object of class `bayesLife.mcmc.set`. Function `has.e0.mcmc` checks the existence of such results. Function `e0.mcmc` extracts a single chain, and `e0.mcmc.list` extracts several or all chains from the simulation results.

### Usage

```
get.e0.mcmc(sim.dir = file.path(getwd(), "bayesLife.output"),  
            chain.ids = NULL, low.memory = TRUE, burnin = 0, verbose = FALSE)
```

```
has.e0.mcmc(sim.dir)
```

```
e0.mcmc(mcmc.set, chain.id = 1)
```

```
e0.mcmc.list(mcmc.set, chain.ids = NULL)
```

**Arguments**

sim.dir	Directory where the simulation results are stored.
chain.ids	Chain identifiers in case only specific chains should be included in the resulting object. By default, all available chains are included.
low.memory	If FALSE full MCMC traces are loaded into memory.
burnin	Burnin used for loading traces. Only relevant, if low.memory=FALSE.
verbose	Logical switching log messages on and off.
chain.id	Chain identifier.
mcmc.set	Object of class <code>bayesLife.mcmc.set</code> .

**Value**

get.e0.mcmc returns an object of class `bayesLife.mcmc.set`. has.e0.mcmc returns a logical value. e0.mcmc returns an object of class `bayesLife.mcmc`, and e0.mcmc.list returns a list of `bayesLife.mcmc` objects.

**Author(s)**

Hana Sevcikova

**See Also**

[bayesLife.mcmc.set](#)

**Examples**

```
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
m <- get.e0.mcmc(sim.dir)
summary(m)

# summary of the world parameters for a single chain
# (the same as above since there is only one chain in this toy example)
summary(e0.mcmc.list(m)[[1]], par.names.cs = NULL)

# the same as
summary(e0.mcmc(m, chain.id = 1), par.names.cs = NULL)
```

---

get.e0.parameter.traces

*Accessing MCMC Parameter Traces*

---

**Description**

Functions for accessing traces of the MCMC parameters, either country-independent or country-specific.

**Usage**

```
get.e0.parameter.traces(mcmc.list, par.names = NULL,
  burnin = 0, thinning.index = NULL, thin = NULL)

get.e0.parameter.traces.cs(mcmc.list, country.obj,
  par.names = NULL, burnin = 0, thinning.index = NULL, thin = NULL)
```

**Arguments**

<code>mcmc.list</code>	List of <code>bayesLife.mcmc</code> objects.
<code>country.obj</code>	Country object list (see <code>get.country.object</code> ).
<code>par.names</code>	Names of country-independent parameters (in case of <code>get.e0.parameter.traces</code> ) or country-specific parameters (in case of <code>get.e0.parameter.traces.cs</code> ) to be included. By default all parameters are included.
<code>burnin</code>	Burn-in indicating how many iterations should be removed from the beginning of each chain.
<code>thinning.index</code>	Index of the traces for thinning. If it is <code>NULL</code> , <code>thin</code> is used. <code>thinning.index</code> does not include <code>burnin</code> and should be flattened over all chains. For example, if there are two MCMC chains of length 1000, <code>burnin=200</code> and we want a sample of length 400, then the value should be <code>thinning.index=seq(1,1600, length=400)</code> .
<code>thin</code>	Alternative to <code>thinning.index</code> . The above example is equivalent to <code>thin=4</code> .

**Value**

Both functions return a matrix with columns being the parameters and rows being the MCMC values, attached to one another in case of multiple chains. `get.e0.parameter.traces` returns country-independent parameters, `get.e0.parameter.traces.cs` returns country-specific parameters.

**Author(s)**

Hana Sevcikova

**See Also**

`e0.coda.list.mcmc` for another way of retrieving parameter traces.

**Examples**

```
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
m <- get.e0.mcmc(sim.dir)
e0.values <- get.e0.parameter.traces(m$mcmc.list, burnin = 10, par.names = "z")
hist(e0.values, main = colnames(e0.values))

e0.values.cs <- get.e0.parameter.traces.cs(m$mcmc.list,
  get.country.object("Canada", meta = m$meta),
  burnin = 10, par.names = "z.c")
hist(e0.values.cs, main = colnames(e0.values.cs))
```

---

get.e0.prediction      *Accessing a Prediction Object*

---

## Description

Function `get.e0.prediction` retrieves results of a prediction and creates an object of class `bayesLife.prediction`. Function `has.e0.prediction` checks an existence of such results. Analogously, functions `get.e0.jmale.prediction` and `has.e0.jmale.prediction` retrieve and check an existence of male predictions from a given female prediction object. Function `available.e0.predictions` lists predictions available in the given simulation directory.

## Usage

```
get.e0.prediction(mcmc = NULL, sim.dir = NULL, joint.male = FALSE,
                 mcmc.dir = NULL, subdir = "predictions")

has.e0.prediction(mcmc = NULL, sim.dir = NULL, subdir = "predictions")

get.e0.jmale.prediction(e0.pred)

has.e0.jmale.prediction(e0.pred)

available.e0.predictions(mcmc = NULL, sim.dir = NULL, full.names = FALSE)
```

## Arguments

<code>mcmc</code>	Object of class <code>bayesLife.mcmc.set</code> used to make the prediction. If it is <code>NULL</code> , the prediction is loaded from directory given by <code>sim.dir</code> .
<code>sim.dir</code>	Directory where the prediction is stored. It should correspond to the value of the <code>output.dir</code> argument used in the <code>e0.predict</code> function. Only relevant if <code>mcmc</code> is <code>NULL</code> .
<code>joint.male</code>	Logical. If <code>TRUE</code> , the function is applied to a male prediction that was generated using the joint female-male model implemented in the function <code>e0.jmale.predict</code> .
<code>mcmc.dir</code>	Optional argument to be used only in a special case when the <code>mcmc</code> object contained in the prediction object was estimated in different directory than in the one to which it points to (for example due to moving or renaming the original directory). The argument causes that the <code>mcmc</code> is redirected to the given directory.
<code>subdir</code>	Subdirectory of <code>sim.dir</code> for this particular prediction.
<code>full.names</code>	Logical. If <code>TRUE</code> , the directory names are given as full paths, otherwise (default) only the base names.
<code>e0.pred</code>	Object of class <code>bayesLife.prediction</code> .

**Details**

If `mcmc` is not `NULL`, the search directory is set to `mcmc$meta$output.dir`. This approach assumes that the prediction was stored in the same directory as the MCMC simulation, i.e. the `output.dir` argument of the `e0.predict` function was set to `NULL`. If it is not the case, the argument `mcmc.dir` should be used.

Usually, all predictions are stored in the subdirectory “predictions” of the simulation directory. If the subdirectory has a different name, the argument `subdir` should be used. This allows to keep multiple predictions in one (MCMC) simulation directory. The function `available.e0.predictions` can be used to view all available predictions in the simulation directory.

Function `get.e0.jmale.prediction` extracts male projections from the `e0.pred` objects (which should be a female prediction object), if the male prediction was generated using the `e0.jmale.predict` function. `has.e0.jmale.prediction` checks if such male prediction was generated.

**Value**

Functions `has.e0.prediction` and `has.e0.jmale.prediction` return a logical indicating if a prediction exists.

Functions `get.e0.prediction` and `get.e0.jmale.prediction` return an object of class `bayesLife.prediction`.

Function `available.e0.predictions` returns a vector of directory names containing `e0` predictions.

**Author(s)**

Hana Sevcikova

**See Also**

[bayesLife.prediction](#), [e0.predict](#), [summary.bayesLife.prediction](#), [e0.jmale.predict](#)

**Examples**

```
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
pred <- get.e0.prediction(sim.dir = sim.dir)
# female prediction summary
summary(pred, country = "Canada")

## Not run:
# male prediction summary
# (works only if a joint male prediction exists - not the case in this toy example)
summary(get.e0.jmale.prediction(pred), country = "Canada")
## End(Not run)
```

---

get.e0.trajectories     *Accessing Trajectories of Life Expectancy*

---

### Description

Function for accessing trajectories of the life expectancy.

### Usage

```
get.e0.trajectories(e0.pred, country)
```

### Arguments

e0.pred	Object of class <a href="#">bayesLife.prediction</a> .
country	Name or numerical code of a country. It can also be given as ISO-2 or ISO-3 characters.

### Details

The function loads trajectories of life expectancy for the given country from disk and returns it as a matrix.

### Value

Array of size the number of projection periods (including the present year) times the number of trajectories. The row names correspond to the mid-years of the prediction periods.

### Author(s)

Hana Sevcikova

### See Also

[bayesLife.prediction](#), [get.e0.prediction](#), [e0.trajectories.table](#)

### Examples

```
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
pred <- get.e0.prediction(sim.dir=sim.dir)
get.e0.trajectories(pred, "Germany")
```

---

get.rege0.prediction *Accessing Subnational Prediction Objects*

---

### Description

Retrieve subnational (regional) prediction results produced by `e0.predict.subnat`, either for one country or for all available countries.

### Usage

```
get.rege0.prediction(sim.dir, country = NULL, method = "ar1", joint.male = FALSE)
```

### Arguments

<code>sim.dir</code>	Simulation directory of the subnational predictions. It corresponds to the argument <code>output.dir</code> in <code>e0.predict.subnat</code> .
<code>country</code>	Numerical country code. If it is not given, all available subnational predictions are retrieved.
<code>method</code>	Method used for generating the projections. It corresponds to the method argument in <code>e0.predict.subnat</code> .
<code>joint.male</code>	Logical. If TRUE, the function is applied to a male prediction that was generated using the joint female-male gap model implemented in the function <code>e0.jmale.predict.subnat</code> .

### Details

Predictions for country  $x$  are assumed to be stored in “`sim.dir/subnat_method/cx`”.

### Value

If argument `country` is given, the function returns an object of class `bayesLife.prediction`. If it is NULL, it returns a list of such objects. Names of the list items are the country codes.

### See Also

[e0.predict.subnat](#)

### Examples

```
# Subnational example data
my.sube0.file <- file.path(find.package("bayesLife"), 'extdata', 'subnational_e0_template.txt')
sube0 <- read.delim(my.sube0.file, check.names = FALSE)
countries <- unique(sube0[, c("country_code", "country_name")])

# Directory with national projections (contains 30 trajectories for each country)
nat.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")

# Subnational projections for all three countries,
# including male projections where female
```

```

# data is used only for demonstration purposes
# (my.e0M.file should contain male e0).
subnat.dir <- tempfile()
e0.predict.subnat(countries$country_code, my.e0.file = my.sube0.file,
  sim.dir = nat.dir, output.dir = subnat.dir, start.year = 2013,
  predict.jmale = TRUE, my.e0M.file = my.sube0.file)

# Retrieve results for all countries
preds <- get.rege0.prediction(subnat.dir)
names(preds)

# View tables of subregions for each country
for(i in 1:nrow(countries)) {
  cat("\n\n", countries$country_name[i], "\n")
  print(get.countries.table(preds[[as.character(countries$country_code[i])]]))
}
# Quantiles for individual subregions for female
e0.trajectories.table(preds[["36"]], "Victoria")

# Retrieve results for one country (Canada)
pred <- get.rege0.prediction(subnat.dir, 124)
e0.trajectories.plot(pred, "Quebec", both.sexes = TRUE)

# Retrieve only male results
predM <- get.rege0.prediction(subnat.dir, 124, joint.male = TRUE)
e0.trajectories.table(predM, "Quebec")

# cleanup
unlink(subnat.dir)

# See more examples in ?e0.predict.subnat

```

---

get.thinned.e0.mcmc     *Creating and Accessing Thinned MCMCs*

---

## Description

The function `get.thinned.e0.mcmc` accesses a thinned and burned version of the given MCMC set. `create.thinned.e0.mcmc` creates such set.

## Usage

```

get.thinned.e0.mcmc(mcmc.set, thin = 1, burnin = 0)

create.thinned.e0.mcmc(mcmc.set, thin = 1, burnin = 0,
  output.dir = NULL, verbose = TRUE)

```

**Arguments**

<code>mcmc.set</code>	Object of class <a href="#">bayesLife.mcmc.set</a> .
<code>thin, burnin</code>	Thinning interval and burnin used for creating or identifying the thinned object.
<code>output.dir</code>	Directory for storing the thinned object. By default it is stored into the same directory as <code>mcmc.set</code> .
<code>verbose</code>	Logical switching log messages on and off.

**Details**

The function `create.thinned.e0.mcmc` is called from `e0.predict` and thus, the resulting object contains exactly the same MCMCs used for generating projections.

The thinning is done as follows: The given burnin is removed from the beginning of each chain in the original MCMC set. Then each chain is thinned by `thin` using equal spacing and all chains are collapsed into one single chain per parameter. They are stored in `output.dir` under the name `'thinned_mcmc_t_b'` where *t* is the value of `thin` and *b* the value of `burnin`.

**Value**

Both functions return an object of class [bayesLife.mcmc.set](#). `get.thinned.e0.mcmc` returns NULL if such object does not exist.

**Author(s)**

Hana Sevcikova

**See Also**

[bayesLife.mcmc.set](#), `e0.predict`

**Examples**

```
## Not run:
sim.dir <- tempfile()
m <- run.e0.mcmc(nr.chains = 2, iter = 60, thin = 2, output.dir = sim.dir, verbose = TRUE)
pr <- e0.predict(m, burnin = 40, predict.jmale = FALSE) # creates thinned MCMCs
mb <- get.thinned.e0.mcmc(m, thin = 2, burnin = 40)
summary(mb, meta.only = TRUE) # length 20 = 2chains x (60-40)iters./2thin

# the same chain as
summary(pr$mcmc.set, meta.only = TRUE)

unlink(sim.dir, recursive=TRUE)
## End(Not run)
```

---

include	<i>Inclusion Codes</i>
---------	------------------------

---

### Description

Datasets containing codes that determine which countries are to be included into a simulation or/and projections.

### Usage

```
data(include_2024)
data(include_2022)
data(include_2019)
data(include_2017)
data(include_2015)
data(include_2012)
data(include_2010)
```

### Format

Data frames containing one record per country or region. It has the following variables:

**country** Name of country or region. Not used.

**country\_code** Numerical Location Code (3-digit codes following ISO 3166-1 numeric standard) - see [https://en.wikipedia.org/wiki/ISO\\_3166-1\\_numeric](https://en.wikipedia.org/wiki/ISO_3166-1_numeric).

**include\_code** Entries for which `include_code=2` are included in MCMC simulations (i.e. estimation of the model parameters). Entries for which `include_code` is 1 or 2 are included in the prediction.

### Details

In a simulation, an `include_*` dataset is selected that corresponds to the given `wpp.year` passed to the function `run.e0.mcmc`. It is merged with an `e0` dataset from the corresponding **wpp** package using the `country_code` column. Thus, the country entries in this dataset should correspond to entries in the `e0F` (`e0M`) dataset.

The package contains also a dataset called `'my_e0_template'` (in `'extdata'` directory) which is a template for user-specified `e0` time series. It has the same structure as the `e0` dataset, except that most of the columns are optional. The only required column is `country_code` (see description of the argument `my.e0.file` in `run.e0.mcmc`).

### Note

In all three datasets, countries affected by AIDS are not included in the estimation, i.e. the `include_code` is set to 3.

### Source

Data provided by the United Nations Population Division.

**Examples**

```
data(include_2019)
head(include_2019)
# select AIDS countries
subset(include_2019, include_code == 3)
```

---

run.e0.mcmc

*Running Bayesian Hierarchical Model for Life Expectancy via Markov Chain Monte Carlo*

---

**Description**

Runs (or continues running) MCMCs for simulating the life expectancy for all countries of the world, using a Bayesian hierarchical model.

**Usage**

```
run.e0.mcmc(sex = c("Female", "Male"), nr.chains = 3, iter = 160000,
  output.dir = file.path(getwd(), "bayesLife.output"),
  thin = 10, replace.output = FALSE, annual = FALSE,
  start.year = 1873, present.year = 2020, wpp.year = 2019,
  my.e0.file = NULL, my.locations.file = NULL, use.wpp.data = TRUE,
  constant.variance = FALSE, seed = NULL,
  parallel = FALSE, nr.nodes = nr.chains, compression.type = 'None',
  verbose = FALSE, verbose.iter = 100, mcmc.options = NULL, ...)
```

```
continue.e0.mcmc(iter, chain.ids = NULL,
  output.dir = file.path(getwd(), "bayesLife.output"),
  parallel = FALSE, nr.nodes = NULL, auto.conf = NULL,
  verbose = FALSE, verbose.iter = 10, ...)
```

**Arguments**

sex	Sex for which to run the simulation.
nr.chains	Number of MCMC chains to run.
iter	Number of iterations to run in each chain. In addition to a single value, it can have the value 'auto' for an automatic assessment of the convergence. In such a case, the function runs for the number of iterations given in the global option auto.conf list (see <a href="#">e0mcmc.options</a> ), then checks if the MCMCs converged (using the auto.conf settings). If it did not converge, the procedure is repeated until convergence is reached or the number of repetition exceeded auto.conf\$max.loops.
output.dir	Directory which the simulation output should be written into.
thin	Thinning interval between consecutive observations to be stored on disk.
replace.output	If TRUE, existing outputs in output.dir will be replaced by results of this simulation.

annual	If TRUE, the model will be trained based on annual data. In such a case, argument <code>my.e0.file</code> must be used to provide the annual observed data.
start.year	Start year for using historical data.
present.year	End year for using historical data.
wpp.year	Year for which WPP data is used. The function loads a package called <code>wppx</code> where $x$ is the <code>wpp.year</code> and uses the <code>e0*</code> datasets.
my.e0.file	File name containing user-specified e0 time series for one or more countries. See Details below.
my.locations.file	File name containing user-specified locations. See Details below.
use.wpp.data	Logical indicating if default WPP data should be used, i.e. if <code>my.e0.file</code> will be matched with the WPP data in terms of time periods and locations. If FALSE, it is assumed that the <code>my.e0.file</code> contains all locations and time periods to be included in the simulation.
constant.variance	Logical indicating if the model should be estimated using constant variance. It should only be used if the standard deviation lowess is to be analysed, see <a href="#">compute.loess</a> .
seed	Seed of the random number generator. If NULL no seed is set. It can be used to generate reproducible results.
parallel	Logical determining if the simulation should run multiple chains in parallel. If it is TRUE, the package <code>snowFT</code> is required.
nr.nodes	Relevant only if <code>parallel</code> is TRUE. It gives the number of nodes for running the simulation in parallel. By default it equals to the number of chains.
compression.type	One of 'None', 'gz', 'xz', 'bz', determining type of a compression of the MCMC files.
verbose	Logical switching log messages on and off.
verbose.iter	Integer determining how often (in number of iterations) log messages are outputted during the estimation.
mcmc.options	List of options that overwrites global MCMC options as defined in <a href="#">e0mcmc.options</a> . Type <code>e0mcmc.options()</code> to view default values.
auto.conf	In <code>continue.e0.mcmc</code> , one can overwrite the global <code>auto.conf</code> option, see <a href="#">e0mcmc.options</a> for its definition. This argument is only used if the function argument <code>iter</code> is set to 'auto'.
...	Additional parameters to be passed to the function <code>snowFT::performParallel</code> , if <code>parallel</code> is TRUE.
chain.ids	Array of chain identifiers that should be resumed. If it is NULL, all existing chains in <code>output.dir</code> are resumed.

## Details

The function `run.e0.mcmc` uses a set of global options (for priors, initial values etc.), possibly modified by the `mcmc.options` argument. One can also modify these options using [e0mcmc.options](#).

Call `e0mcmc.options()` for the full set of options. Function `continue.e0.mcmc` inherits its set of options from the corresponding `run.e0.mcmc` call.

The function `run.e0.mcmc` creates an object of class `bayesLife.mcmc.meta` and stores it in `output.dir`. It launches `nr.chains` MCMCs, either sequentially or in parallel. Parameter traces of each chain are stored as (possibly compressed) ASCII files in a subdirectory of `output.dir`, called `mcx` where `x` is the identifier of that chain. There is one file per parameter, named after the parameter with the suffix “.txt”, possibly followed by a compression suffix if `compression.type` is given. Country-specific parameters have the suffix `_countryc` where `c` is the country code. In addition to the trace files, each `mcx` directory contains the object `bayesLife.mcmc` in binary format. All chain-specific files are written into disk after the first, last and each  $i$ -th (thinned) iteration, where  $i$  is given by the global option `buffer.size`.

Using the function `continue.e0.mcmc` one can continue simulating an existing MCMCs by `iter` iterations for either all or selected chains. The global options used for generating the existing MCMCs will be used. Only the `auto.conf` option can be overwritten by passing the new value as an argument.

The function loads observed data (further denoted as WPP dataset), depending on the specified `sex`, from the `e0F (e0M)` and `e0F_supplemental (e0M_supplemental)` datasets in a `wpp:x` package where `x` is the `wpp.year`. It is then merged with the `include` dataset that corresponds to the same `wpp.year`. The argument `my.e0.file` can be used to overwrite those default data. If `use.wpp.data` is `FALSE`, it fully replaces the default dataset. Otherwise (by default), such a file can include a subset of countries contained in the WPP dataset, as well as a set of new countries. In the former case, the function replaces the corresponding country data from the WPP dataset with values in this file. Only columns are replaced that match column names of the WPP dataset, and in addition, columns ‘last.observed’ and ‘include\_code’ are used, if present. Countries are merged with WPP using the column ‘country\_code’. In addition, in order the countries to be included in the simulation, in both cases (whether they are included in the WPP dataset or not), they must be contained in the table of locations (`UNlocations`). In addition, their corresponding ‘include\_code’ must be set to 2. If the column ‘include\_code’ is present in `my.e0.file`, its value overwrites the default include code, unless is -1.

If `annual` is `TRUE` the default WPP dataset is not used and the `my.e0.file` argument must provide the dataset to be used for estimation. Its time-related columns should be single years.

The default UN table of locations mentioned above can be overwritten/extended by using a file passed as the `my.locations.file` argument. Such a file must have the same structure as the `UNlocations` dataset. Entries in this file will overwrite corresponding entries in `UNlocations` matched by the column ‘country\_code’. If there is no such entry in the default dataset, it will be appended. This option of appending new locations is especially useful in cases when `my.e0.file` contains new countries/regions that are not included in `UNlocations`. In such a case, one must provide a `my.locations.file` with a definition of those countries/regions.

For simulation of the hyperparameters of the Bayesian hierarchical model, all countries are used that are included in the WPP dataset, possibly complemented by the `my.e0.file`, that have `include_code` equal to 2. The hyperparameters are used to simulate country-specific parameters, which is done for all countries with `include_code` equal 1 or 2. The following values of `include_code` in `my.e0.file` are recognized: -1 (do not overwrite the default include code), 0 (ignore), 1 (include in prediction but not estimation), 2 (include in both, estimation and prediction). Thus, the set of countries included in the estimation and prediction can be fully specified by the user.

Optionally, `my.e0.file` can contain a column called `last.observed` containing the year of the last observation for each country. In such a case, the code would ignore any data after that time

point. Furthermore, the function `e0.predict` fills in the missing values using the median of the BHM procedure (stored in `e0.matrix.reconstructed` of the `bayesLife.prediction` object). For last. observed values that are below a middle year of a time interval  $[t_i, t_{i+1}]$  (computed as  $t_i + 3$ ) the last valid data point is the time interval  $[t_{i-1}, t_i]$ , whereas for values larger equal a middle year, the data point in  $[t_i, t_{i+1}]$  is valid.

The package contains a dataset called ‘my\_e0\_template’ (in ‘extdata’ directory) which is a template for user-specified my.e0.file.

## Value

An object of class `bayesLife.mcmc.set` which is a list with two components:

<code>meta</code>	An object of class <code>bayesLife.mcmc.meta</code> .
<code>mcmc.list</code>	A list of objects of class <code>bayesLife.mcmc</code> , one for each MCMC.

run.e0.mcmc.extra      *Run MCMC for Extra Countries, Areas or Regions*

---

## Description

Run MCMC for extra countries, areas or regions. It uses the posterior distribution of model hyperparameters from an existing simulation to generate country-specific parameters.

**Usage**

```
run.e0.mcmc.extra(sim.dir = file.path(getwd(), "bayesLife.output"),
  countries = NULL, my.e0.file = NULL,
  iter = NULL, thin = 1, burnin = 0,
  parallel = FALSE, nr.nodes = NULL, my.locations.file = NULL,
  country.overwrites = NULL, verbose = FALSE, verbose.iter = 100, ...)
```

**Arguments**

<code>sim.dir</code>	Directory with an existing simulation.
<code>countries</code>	Vector of country codes. These include codes of areas and regions (see column <code>country_code</code> in <a href="#">UNlocations</a> ).
<code>my.e0.file</code>	File name containing user-specified time series of life expectancy for countries for which the simulation should run (see Details below).
<code>iter</code>	Number of iterations to be used for sampling from the posterior distribution of the hyperparameters. By default, the number of (possibly thinned) iterations used in the existing simulation is taken.
<code>thin</code>	Thinning interval for sampling from the posterior distribution of the hyperparameters.
<code>burnin</code>	Number of iterations discarded before sampling from the posterior distribution of the hyperparameters.
<code>parallel</code>	Logical determining if the simulation should run multiple chains in parallel.
<code>nr.nodes</code>	Relevant only if <code>parallel</code> is TRUE. It gives the number of nodes for running the simulation in parallel. By default it equals to the number of chains contained in the existing simulation.
<code>my.locations.file</code>	File name containing user-specified locations. See Details below.
<code>country.overwrites</code>	This argument allows to overwrite some of the prior parameters for specific countries, stored in the global option of the same name, see <a href="#">e0mcmc.options</a> . It is a data frame where each row corresponds to one country. Rows corresponding to countries that are not processed in this function are ignored.
<code>verbose</code>	Logical switching log messages on and off.
<code>verbose.iter</code>	Integer determining how often (in number of iterations) log messages are out-putted during the estimation.
<code>...</code>	Additional parameters to be passed to the function <code>snowFT::performParallel</code> , if <code>parallel</code> is TRUE.

**Details**

The function can be used to make predictions for countries, areas or regions (further denoted as ‘countries’) that were not included in the MCMC estimation (invoked by [run.e0.mcmc](#)). It creates MCMC traces for country-specific parameters. The purpose of this function is to have country-specific parameters available in order to be able to generate projections for additional countries or their aggregations, without having to re-run the often time-expensive MCMC simulation.

The set of countries to be considered by this function can be given either by their codes, using the argument `countries`, in which case the countries must be included in the UN WPP `e0` dataset. Or, it can be given by a user-specific file, using the argument `my.e0.file`. The function considers a union of both arguments. The function will ignore all countries that were used in the existing MCMC simulation for estimating the hyperparameters. Countries that already own country-specific parameters (e.g. because they were included in `my.e0.file` passed to `run.e0.mcmc`) get their parameters recomputed. Note that all countries must be included in the `UNlocations` dataset, but unlike in `run.e0.mcmc`, their `include_code` is ignored. As in the case of `run.e0.mcmc`, the default dataset of locations `UNlocations` can be overwritten using a file of the same structure as `UNlocations` passed via the `my.locations.file` argument. This file should be especially used, if `e0` is simulated for new locations that are not included in `UNlocations`.

### Value

An object of class `bayesLife.mcmc.set`.

### Note

If there is an existing projection for the directory `sim.dir`, use `e0.predict.extra` to obtain projections for the extra countries used in this function.

### Author(s)

Hana Sevcikova

### See Also

`run.e0.mcmc`, `e0.predict.extra`

### Examples

```
## Not run:
m <- run.e0.mcmc(nr.chains = 1, iter = 20, thin = 1, verbose = TRUE)
m <- run.e0.mcmc.extra(countries = c(908,924), burnin = 10, verbose = TRUE)
summary(m, country = 924)
pred <- e0.predict(burnin = 10, verbose = TRUE)
summary(pred, country = 908)
## End(Not run)
```

---

summary.bayesLife.convergence

*Summary of a Life Expectancy Convergence Object*

---

### Description

Summary of an object of class `bayesLife.convergence` created using the `e0.diagnose` function. It gives an overview about parameters that did not converge.

**Usage**

```
## S3 method for class 'bayesLife.convergence'
summary(object, expand = FALSE, ...)
```

**Arguments**

object	Object of class <a href="#">bayesLife.convergence</a> .
expand	By default, the function does not show parameters for each country for which there was no convergence, if the status is 'red'. This argument can switch that option on.
...	Not used.

**Author(s)**

Hana Sevcikova

**See Also**

[e0.diagnose](#)

---

```
summary.bayesLife.mcmc.set
```

*Summary Statistics for Life Expectancy MCMCs*

---

**Description**

Summary of an object [bayesLife.mcmc.set](#) or [bayesLife.mcmc](#), computed via `run.e0.mcmc`. It can be obtained either for all countries or for a specific country, and either for all parameters or for specific parameters. The function uses the [summary.mcmc](#) function of the **cod**a package.

**Usage**

```
## S3 method for class 'bayesLife.mcmc.set'
summary(object, country = NULL, chain.id = NULL,
        par.names = NULL, par.names.cs = NULL, meta.only = FALSE,
        thin = 1, burnin = 0, ...)

## S3 method for class 'bayesLife.mcmc'
summary(object, country = NULL,
        par.names = NULL, par.names.cs = NULL, thin = 1, burnin = 0, ...)
```

**Arguments**

object	Object of class <code>bayesLife.mcmc.set</code> or <code>bayesLife.mcmc</code> .
country	Country name or code if a country-specific summary is desired. It can also be given as ISO-2 or ISO-3 characters.
chain.id	Identifiers of MCMC chains. By default, all chains are considered.
par.names	Country independent parameters to be included in the summary. Run <code>e0.parameter.names()</code> for defaults.
par.names.cs	Country-specific parameters to be included in the summary. Run <code>e0.parameter.names.cs()</code> for defaults.
meta.only	Logical. If it is TRUE, only meta information of the simulation is included.
thin	Thinning interval. Only used if larger than the <code>thin</code> argument used in <code>run.e0.mcmc</code> .
burnin	Number of iterations to be discarded from the beginning of each chain before computing the summary.
...	Additional arguments passed to the <code>summary.mcmc</code> function of the <b>coda</b> package.

**Examples**

```
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
m <- get.e0.mcmc(sim.dir)
summary(m, country="Czechia", burnin=20)

# names and codes of countries included
head(get.countries.table(m, iso = TRUE))
# using an ISO code
summary(m, country="MG", burnin=20)
```

---

```
summary.bayesLife.prediction
```

*Summary of a Prediction of the Life Expectancy*

---

**Description**

Country-specific summary of an object of class `bayesLife.prediction`, created using the function `e0.predict`. The summary contains the mean, standard deviation and several commonly used quantiles of the simulated trajectories.

## Usage

```
## S3 method for class 'bayesLife.prediction'  
summary(object, country = NULL, compact = TRUE, ...)
```

## Arguments

object	Object of class <a href="#">bayesLife.prediction</a> .
country	Country name or code.
compact	Logical switching between a smaller and larger number of displayed quantiles.
...	Not used.

## Author(s)

Hana Sevcikova

## See Also

[bayesLife.prediction](#)

## Examples

```
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")  
pred <- get.e0.prediction(sim.dir=sim.dir)  
summary(pred, country="Iceland")  
  
# names and codes of countries included  
tail(get.countries.table(pred, iso = TRUE), 20)  
  
# using an ISO code  
summary(pred, country="CHE")
```

---

write.e0.projection.summary

*Writing Projection Summary Files*

---

## Description

The function creates two files containing projection summaries, such as the median, the lower and upper bound of the 80 and 90% probability intervals, respectively, and the constant variant. One file is in a user-friendly format, whereas the other is in a UN-specific format with internal coding of the time and the variants.

## Usage

```
write.e0.projection.summary(dir = file.path(getwd(), "bayesLife.output"),  
  subdir = "predictions", output.dir = NULL, revision = NULL, adjusted = FALSE)
```

**Arguments**

dir	Directory containing the prediction object. It should correspond to the output.dir argument of the <code>e0.predict</code> function.
subdir	Subdirectory of dir containing the predictions.
output.dir	Directory in which the resulting file will be stored. If NULL the same directory is used as for the prediction.
revision	UN revision number. If NULL it is determined from the corresponding WPP year: WPP 2008 corresponds to revision 13, every subsequent WPP increases the revision number by one. Used as a constant in the second file only.
adjusted	Logical. By default the function writes summary using the original BHM projections. If the projection medians are adjusted (using e.g. <code>e0.median.set</code> ), setting this argument to TRUE causes writing the adjusted projections.

**Details**

The first file that the function creates is called ‘projection\_summary\_user\_friendly.csv’, it is a comma-separated table with the following columns:

**“country\_name”**: country name

**“country\_code”**: country code

**“variant”**: name of the variant, such as “median”, “lower 80”, “upper 80”, “lower 95”, “upper 95”, “constant”

**period1**: e.g. “2010-2015”: life expectancy for the first time period

**period2**: e.g. “2015-2020”: life expectancy for the second time period

... further columns with life expectancy projections

The second file, called ‘projection\_summary.csv’, also comma-separated table, contains the same information as above in a UN-specific format:

**“RevID”**: revision number, passed to the function as an argument;

**“VarID”**: variant identifier, extracted from the `UN_variants` dataset in the `bayesTFR` package;

**“LocID”**: country code;

**“TimeID”**: time identifier, extracted from the `UN_time` dataset in the `bayesTFR` package;

**“e0”**: the life expectancy for this variant, location and time period.

If the simulation directory contains joint male predictions, summary files for those are created as well. In such a case, if output.dir is given, separate subdirectories for female and male are created.

**Note**

This function is automatically called from the `e0.predict` and `e0.jmale.predict` functions, therefore in standard cases it will not be needed to call it directly.
