Package: gravmagsubs (via r-universe)

October 7, 2024

Type Package

Title Gravitational and Magnetic Attraction of 3-D Vertical Rectangular Prisms

Version 1.0.1

Description Computes the gravitational and magnetic anomalies generated by 3-D vertical rectangular prisms at specific observation points using the method of Plouff (1976) <doi:10.1190/1.1440645>.

gravmagsubs-package	*Gravitational and magnetic attraction of 3-D vertical rectangular prisms*

Description

The package `gravmagsubs` provides tools for computing the gravitational and magnetic anomalies generated by 3-D vertical rectangular prisms at specific observation points. The package consists of two functions:

- `rectprismgrav` : Computes the gravitational attraction of 3-D right rectangular prisms.
- `rectprismmag` : Computes the magnetic effect of 3-D right rectangular prisms.

Each function can compute the total anomaly of a series of N prisms at M observation points.

Each function also has a logical flag `bycell` (default `FALSE`). If `bycell=TRUE`, the function returns the contribution from each individual prism.

rectprismgrav	*rectprismgrav*

Description

Calculates the graviational attraction of 3-D rectangular prisms. Calculates anomalies of N prisms at M observation stations.

Stations cannot be positioned on the edge of a prism.

Coordinates of stations and prisms are assumed to share a common coordinate system.

Usage

```
rectprismgrav(xstation, ystation, zstation, xmin, xmax, ymin, ymax,
                    zdeep, zshallow, deltarho, bycell=FALSE)
```

Arguments

xstation	vector of length M with the x-coordinates of each station, in km, positive east;
ystation	vector of length M with the y-coordinates of each station, in km, positive north;
zstation	vector of length M with the z-coordinates of each station, in km, positive up;
xmin	vector of length N with the minimum x-coordinates of each prism, in km, positive east;

xmax	vector of length N with the maximum x-coordinates of each prism, in km, positive east;
ymin	vector of length N with the minimum y-coordinates of each prism, in km, positive north;
ymax	vector of length N with the maximum y-coordinates of each prism, in km, positive north;
zdeep	vector of length N with the bottom z-coordinates of each prism, in km, positive up;
zshallow	vector of length N with the top z-coordinates of each prism, in km, positive up;
deltarho	vector of length N with the density contrast of each prism, in grams per cubic centimeter (g/cc);
bycell	returns M-by-N matrix with anomaly values generated by individual prisms (default FALSE).

Value

Returns a matrix of length M rows.

If bycell=FALSE, there will be M rows and 1 column, and the element in the i-th row represents the total gravity anomaly generated by all N prisms as observed at the i-th station.

If bycell=TRUE, the matrix will have M rows and N columns, with the element [i,j] representing the anomaly value generated by the j-th prism as observed at the i-th station.

Examples

```
###########################################################
## gravity anomaly of a single prism at a single point ##

# location of the point where the gravity anomaly will be calculated
gravstation <- data.frame(x=0, y=0, z=0)

# the rectangular prism is defined by its six edges
prism1 <- data.frame(xmin=-5, xmax=5,
                     ymin=-5, ymax=5,
                     zmin=-10, zmax=-5)

# density contrast in g/cc
drho <- 0.3
```

```
gravanom <- rectprismgrav(gravstation$x, gravstation$y, gravstation$z,
                          prism1$xmin, prism1$xmax,
                          prism1$ymin, prism1$ymax,
                          prism1$zmin, prism1$zmax, drho)

#########################################################
```

---

rectprismmag   *rectprismmag*

Description

Calculates the magnetic effect of 3-D rectangular prisms. Calculates anomalies of N prisms at M observation stations.

Stations cannot be positioned inside a prism, or on its edges or faces. Stations cannot be positioned directly below the corners of a prism.

Coordinates of stations and prisms are assumed to share a common coordinate system.

Returns total field magnetic anomaly in nanoteslas (nT).

N.B. Demagnetization effects are ignored in this subroutine.

Usage

```
rectprismmag(xstation, ystation, zstation, xmin, xmax, ymin, ymax,
             zdeep, zshallow, suscvolsi, nrmstr, nrmincl, nrmdecl,
             fieldtotal, fieldincl, fielddecl, bycell=FALSE)
```

Arguments

xstation	vector of length M with the x-coordinates of each station, in km, positive east;
ystation	vector of length M with the y-coordinates of each station, in km, positive north;
zstation	vector of length M with the z-coordinates of each station, in km, positive up;
xmin	vector of length N with the minimum x-coordinates of each prism, in km, positive east;
xmax	vector of length N with the maximum x-coordinates of each prism, in km, positive east;
ymin	vector of length N with the minimum y-coordinates of each prism, in km, positive north;
ymax	vector of length N with the maximum y-coordinates of each prism, in km, positive north;
zdeep	vector of length N with the bottom z-coordinates of each prism, in km, positive up;
zshallow	vector of length N with the top z-coordinates of each prism, in km, positive up;

suscvolsi	vector of length N with the volume susceptibility (unitless);
nrmstr	vector of length N with the remanent magnetization of each prism, in Amperes per meter (A/m);
nrmincl	vector of length N with the inclination angle of the remanent magnetization for each prism, in degrees, positive below horizontal;
nrmdecl	vector of length N with the declination angle of the remanent magnetization for each prism, in degrees, positive east of true north;
fieldtotal	vector of length N with the Earth's field intensity at each prism, in nanoteslas (nT);
fieldincl	vector of length N with the Earth's field inclination at each prism, in degrees, positive below horizontal;
fielddecl	vector of length N with the Earth's field declination at each prism, in degrees, positive east of true north;
bycell	returns M-by-N matrix with anomaly values generated by individual prisms (default FALSE).

Value

Returns a matrix of length M rows.

If bycell=FALSE, there will be M rows and 1 column, and the element in the i-th row represents the total magnetic anomaly generated by all N prisms as observed at the i-th station.

If bycell=TRUE, the matrix will have M rows and N columns, with the element [i,j] representing the anomaly value generated by the j-th prism as observed at the i-th station.
