Package: odbc (via r-universe)

October 4, 2024

Title Connect to ODBC Compatible Databases (using the DBI Interface)

Version 1.5.0

Description A DBI-compatible interface to ODBC databases.

License MIT + file LICENSE

URL https://odbc.r-dbi.org, https://github.com/r-dbi/odbc,
https://solutions.posit.co/connections/db/

BugReports https://github.com/r-dbi/odbc/issues

Depends R (>= 3.6.0)

Imports bit64, blob (>= 1.2.0), cli, DBI (>= 1.0.0), hms, lifecycle,
methods, Rcpp (>= 0.12.11), rlang (>= 1.1.0)

Suggests covr, DBItest, knitr, magrittr, rmarkdown, RSQLite, testthat
(>= 3.0.0), tibble, withr

LinkingTo Rcpp

ByteCompile true

Config/Needs/check pkgbuild

databricks   *Helper for Connecting to Databricks via ODBC*

Description

Connect to Databricks clusters and SQL warehouses via the Databricks ODBC driver.

In particular, the custom dbConnect() method for the Databricks ODBC driver implements a subset of the Databricks client unified authentication model, with support for personal access tokens, OAuth machine-to-machine credentials, and OAuth user-to-machine credentials supplied via Posit Workbench or the Databricks CLI on desktop. All of these credentials are detected automatically if present using standard environment variables.

Usage

```
databricks()

## S4 method for signature 'DatabricksOdbcDriver'
dbConnect(
  drv,
  httpPath,
  workspace = Sys.getenv("DATABRICKS_HOST"),
  useNativeQuery = TRUE,
  driver = NULL,
  HTTPPath,
  uid = NULL,
  pwd = NULL,
  ...
)
```

Arguments

drv	an object that inherits from [DBIDriver](#), or an existing [DBIConnection](#) object (in order to clone an existing connection).
httpPath, HTTPPath	
	To query a cluster, use the HTTP Path value found under `Advanced Options > JDBC/ODBC` in the Databricks UI. For SQL warehouses, this is found under `Connection Details` instead.
workspace	The URL of a Databricks workspace, e.g. `"https://example.cloud.databricks.com"`.
useNativeQuery	Suppress the driver's conversion from ANSI SQL 92 to HiveSQL? The default (`TRUE`), gives greater performance but means that paramterised queries (and hence `dbWriteTable()`) do not work.
driver	The name of the Databricks ODBC driver, or `NULL` to use the default name.
uid, pwd	Manually specify a username and password for authentication. Specifying these options will disable automated credential discovery.
...	Further arguments passed on to [dbConnect()](#).

Value

An `OdbcConnection` object with an active connection to a Databricks cluster or SQL warehouse.

Examples

```
## Not run:
DBI::dbConnect(
  odbc::databricks(),
  httpPath = "sql/protocolv1/o/4425955464597947/1026-023828-vn51jugj"
)

## End(Not run)
```

DBI-tables	*Convenience functions for reading/writing DBMS tables*

Description

Convenience functions for reading/writing DBMS tables

Usage

```
## S4 method for signature 'OdbcConnection,character,data.frame'
dbWriteTable(
  conn,
  name,
  value,
  overwrite = FALSE,
  append = FALSE,
  temporary = FALSE,
  row.names = NULL,
  field.types = NULL,
  batch_rows = getOption("odbc.batch_rows", NA),
  ...
)

## S4 method for signature 'OdbcConnection,Id,data.frame'
dbWriteTable(
  conn,
  name,
  value,
  overwrite = FALSE,
  append = FALSE,
  temporary = FALSE,
  row.names = NULL,
  field.types = NULL,
  batch_rows = getOption("odbc.batch_rows", NA),
  ...
)

## S4 method for signature 'OdbcConnection,SQL,data.frame'
dbWriteTable(
  conn,
  name,
  value,
  overwrite = FALSE,
  append = FALSE,
  temporary = FALSE,
  row.names = NULL,
  field.types = NULL,
```

```
  batch_rows = getOption("odbc.batch_rows", NA),
  ...
)

## S4 method for signature 'OdbcConnection'
dbAppendTable(
  conn,
  name,
  value,
  batch_rows = getOption("odbc.batch_rows", NA),
  ...,
  row.names = NULL
)

## S4 method for signature 'OdbcConnection'
sqlCreateTable(
  con,
  table,
  fields,
  row.names = NA,
  temporary = FALSE,
  ...,
  field.types = NULL
)
```

Arguments

conn	a [OdbcConnection](#) object, produced by [DBI::dbConnect()](#)
name	a character string specifying a table name. Names will be automatically quoted so you can use any sequence of characters, not just any valid bare table name.
value	A data.frame to write to the database.
overwrite	Allow overwriting the destination table. Cannot be TRUE if append is also TRUE.
append	Allow appending to the destination table. Cannot be TRUE if overwrite is also TRUE.
temporary	If TRUE, will generate a temporary table statement.
row.names	Either TRUE, FALSE, NA or a string.
	If TRUE, always translate row names to a column called "row_names". If FALSE, never translate row names. If NA, translate rownames only if they're a character vector.
	A string is equivalent to TRUE, but allows you to override the default name.
	For backward compatibility, NULL is equivalent to FALSE.
field.types	Additional field types used to override derived types.
batch_rows	The number of rows to retrieve. Defaults to NA, which is set dynamically to the minimum of 1024 and the size of the input. Depending on the database, driver, dataset and free memory setting this to a lower value may improve performance.
...	Other arguments used by individual methods.

con   A database connection.

table   The table name, passed on to [dbQuoteIdentifier()](). Options are:

- a character string with the unquoted DBMS table name, e.g. `"table_name"`,
- a call to [Id()]() with components to the fully qualified table name, e.g. `Id(schema = "my_schema", table = "table_name")`
- a call to [SQL()]() with the quoted and fully qualified table name given verbatim, e.g. `SQL('"my_schema"."table_name"')`

fields   Either a character vector or a data frame.

A named character vector: Names are column names, values are types. Names are escaped with [dbQuoteIdentifier()](). Field types are unescaped.

A data frame: field types are generated using [dbDataType()]().

Examples

```
## Not run:
library(DBI)
con <- dbConnect(odbc::odbc())
dbListTables(con)
dbWriteTable(con, "mtcars", mtcars, temporary = TRUE)
dbReadTable(con, "mtcars")

dbListTables(con)
dbExistsTable(con, "mtcars")

# A zero row data frame just creates a table definition.
dbWriteTable(con, "mtcars2", mtcars[0, ], temporary = TRUE)
dbReadTable(con, "mtcars2")

dbDisconnect(con)

## End(Not run)
```

---

dbListTables,OdbcConnection-method

List remote tables and fields for an ODBC connection

Description

dbListTables() provides names of remote tables accessible through this connection; dbListFields() provides names of columns within a table.

Usage

```
## S4 method for signature 'OdbcConnection'
dbListTables(
  conn,
  catalog_name = NULL,
```

```
    schema_name = NULL,
    table_name = NULL,
    table_type = NULL,
    ...
  )
```

Arguments

conn	A [DBIConnection](#) object, as returned by [dbConnect()](#).
catalog_name, schema_name, table_name	
	Catalog, schema, and table names.
	By default, `catalog_name`, `schema_name` and `table_name` will automatically escape underscores to ensure that you match exactly one table. If you want to search for multiple tables using wild cards, you will need to use `odbcConnectionTables()` directly instead.
table_type	The type of the table to return, the default returns all table types.
...	Other parameters passed on to methods.

Value

A character vector of table or field names respectively.

---

isTempTable	*Helper method used to determine if a table identifier is that of a temporary table.*

Description

Currently implemented only for select back-ends where we have a use for it (SQL Server, for example). Generic, in case we develop a broader use case.

Usage

```
isTempTable(conn, name, ...)

## S4 method for signature 'OdbcConnection,Id'
isTempTable(conn, name, ...)

## S4 method for signature 'OdbcConnection,SQL'
isTempTable(conn, name, ...)
```

Arguments

conn	OdbcConnection
name	Table name
...	additional parameters to methods

---

odbc   *Connect to a database via an ODBC driver*

Description

The dbConnect() method documented here is invoked when [DBI::dbConnect()](#) is called with
the first argument odbc(). Connecting to a database via an ODBC driver is likely the first step
in analyzing data using the odbc package; for an overview of package concepts, see the *Overview*
section below.

Usage

```
odbc()

## S4 method for signature 'OdbcDriver'
dbConnect(
  drv,
  dsn = NULL,
  ...,
  timezone = "UTC",
  timezone_out = "UTC",
  encoding = "",
  bigint = c("integer64", "integer", "numeric", "character"),
  timeout = 10,
  driver = NULL,
  server = NULL,
  database = NULL,
  uid = NULL,
  pwd = NULL,
  dbms.name = NULL,
  attributes = NULL,
  interruptible = getOption("odbc.interruptible", interactive()),
  .connection_string = NULL
)
```

Arguments

drv	An OdbcDriver, from odbc().
dsn	The data source name. For currently available options, see the name column of [odbcListDataSources()](#) output.
...	Additional ODBC keywords. These will be joined with the other arguments to form the final connection string.
	Note that ODBC parameter names are case-insensitive so that (e.g.) DRV and drv are equivalent. Since this is different to R and a possible source of confusion, odbc will error if you supply multiple arguments that have the same name when case is ignored.

Any values containing a leading or trailing space, a =, ;, {, or } are likely to
require quoting. Use `quote_value()` for a fairly standard approach or see your
driver documentation for specifics.

timezone   The server time zone. Useful if the database has an internal timezone that
                  is *not* 'UTC'. If the database is in your local timezone, set this argument to
                  `Sys.timezone()`. See `OlsonNames()` for a complete list of available time zones
                  on your system.

timezone_out   The time zone returned to R. If you want to display datetime values in the local
                  timezone, set to `Sys.timezone()`.

encoding   The text encoding used on the Database. If the database is not using UTF-8 you
                  will need to set the encoding to get accurate re-encoding. See `iconvlist()` for
                  a complete list of available encodings on your system. Note strings are always
                  returned `UTF-8` encoded.

bigint   The R type that `SQL_BIGINT` types should be mapped to. Default is bit64::integer64,
                  which allows the full range of 64 bit integers.

timeout   Time in seconds to timeout the connection attempt. Setting a timeout of `Inf`
                  indicates no timeout. Defaults to 10 seconds.

driver   The ODBC driver name or a path to a driver. For currently available options, see
                  the name column of `odbcListDrivers()` output.

server   The server hostname. Some drivers use `Servername` as the name for this argu-
                  ment. Not required when configured for the supplied dsn.

database   The database on the server. Not required when configured for the supplied dsn.

uid   The user identifier. Some drivers use `username` as the name for this argument.
                  Not required when configured for the supplied dsn.

pwd   The password. Some drivers use `password` as the name for this argument. Not
                  required when configured for the supplied dsn.

dbms.name   The database management system name. This should normally be queried au-
                  tomatically by the ODBC driver. This name is used as the class name for the
                  OdbcConnection object returned from `dbConnect()`. However, if the driver
                  does not return a valid value, it can be set manually with this parameter.

attributes   A list of connection attributes that are passed prior to the connection being es-
                  tablished. See ConnectionAttributes.

interruptible   Logical. If `TRUE` calls to SQLExecute and SQLExecuteDirect can be inter-
                  rupted when the user sends SIGINT (ctrl-c). Otherwise, they block. De-
                  faults to `TRUE` in interactive sessions, and `FALSE` otherwise. It can be set ex-
                  plicitly either by manipulating this argument, or by setting the global option
                  `odbc.interruptible`.

.connection_string
                  A complete connection string, useful if you are copy pasting it from another
                  source. If this argument is used, any additional arguments will be appended to
                  this string.

Connection strings

Internally, dbConnect() creates a connection string using the supplied arguments. Connection string keywords are driver-dependent; the arguments documented here are common, but some drivers may not accept them.

Alternatively to configuring DSNs and driver names with the driver manager, you can pass a complete connection string directly as the .connection_string argument. The Connection Strings Reference is a useful resource that has example connection strings for a large variety of databases.

Overview

The odbc package is one piece of the R interface to databases with support for ODBC:

The package supports any **Database Management System (DBMS)** with ODBC support. Support for a given DBMS is provided by an **ODBC driver**, which defines how to interact with that DBMS using the standardized syntax of ODBC and SQL. Drivers can be downloaded from the DBMS vendor or, if you're a Posit customer, using the professional drivers. To manage information about each driver and the data sources they provide access to, our computers use a **driver manager**. Windows is bundled with a driver manager, while MacOS and Linux require installation of one; this package supports the unixODBC driver manager.

In the **R interface**, the DBI package provides a front-end while odbc implements a back-end to communicate with the driver manager. The odbc package is built on top of the nanodbc C++ library.

Interfacing with DBMSs using R and odbc involves three high-level steps:

1. *Configure drivers and data sources*: the functions odbcListDrivers() and odbcListDataSources() help to interface with the driver manager.

2. *Connect to a database*: The dbConnect() function, called with the first argument odbc(), connects to a database using the specified ODBC driver to create a connection object.

3. *Interface with connections*: The resulting connection object can be passed to various functions to retrieve information on database structure (dbListTables()), iteratively develop queries (dbSendQuery(), dbColumnInfo()), and query data objects (dbFetch()).

Learn more

To learn more about databases:

- "Best Practices in Working with Databases" documents how to use the odbc package with various popular databases.

- Microsoft's "Introduction to ODBC" is a thorough resource on the ODBC interface.

odbcConnectionColumns_,Snowflake,character-method
Connecting to Snowflake via ODBC

Description

odbcConnectionColumns():

If the catalog, or the schema arguments are NULL, attempt to infer by querying for CURRENT_DATABASE()
and CURRENT_SCHEMA(). We do this to aid with performance, as the SQLColumns method
is more performant when restricted to a particular DB/schema.

Usage

```
## S4 method for signature 'Snowflake,character'
dbExistsTableForWrite(conn, name, ..., catalog_name = NULL, schema_name = NULL)
```

Arguments

conn	A [DBIConnection](#) object, as returned by [dbConnect()](#).
name	The table name, passed on to [dbQuoteIdentifier()](#). Options are:

- a character string with the unquoted DBMS table name, e.g. "table_name",
- a call to [Id()](#) with components to the fully qualified table name, e.g. Id(schema = "my_schema", table = "table_name")
- a call to [SQL()](#) with the quoted and fully qualified table name given verbatim, e.g. SQL('"my_schema"."table_name"')

...	Other parameters passed on to methods.
catalog_name, schema_name	
	Catalog and schema names.

---

odbcDataType   *Return the corresponding ODBC data type for an R object*

Description

This is used when creating a new table with dbWriteTable(). Databases with default methods
defined are:

- MySQL
- PostgreSQL
- SQL Server
- Oracle
- SQLite

- Spark
- Hive
- Impala
- Redshift
- Vertica
- BigQuery
- Teradata
- Access
- Snowflake

Usage

```
odbcDataType(con, obj, ...)
```

Arguments

con   A driver connection object, as returned by `dbConnect()`.

obj   An R object.

...   Additional arguments passed to methods.

Details

If you are using a different database and `dbWriteTable()` fails with a SQL parsing error the default method is not appropriate, you will need to write a new method. The object type for your method will be the database name retrieved by `dbGetInfo(con)$dbms.name`. Use the documentation provided with your database to determine appropriate values for each R data type.

Value

Corresponding SQL type for the `obj`.

---

odbcListColumns   *List columns in an object.*

Description

Lists the names and types of each column (field) of a specified object.

Usage

```
odbcListColumns(connection, ...)
```

Arguments

connection A connection object, as returned by `dbConnect()`.

...   Parameters specifying the object.

Details

The object to inspect must be specified as one of the arguments (e.g. table = "employees"); depending on the driver and underlying data store, additional specification arguments may be required.

Value

A data frame with name and type columns, listing the object's fields.

---

odbcListConfig   *List locations of ODBC configuration files*

Description

On MacOS and Linux, odbc uses the unixODBC driver manager to manage information about driver and data sources. This helper returns the filepaths where the driver manager will look for that information.

This function is a wrapper around the command line call odbcinst -j.

Windows does not use .ini configuration files; this function will return a 0-length vector on Windows.

Usage

```
odbcListConfig()
```

See Also

The odbcListDrivers() and odbcListDataSources() helpers return information on the contents of odbcinst.ini and odbc.ini files, respectively.

Learn more about unixODBC and the odbcinst utility here.

Examples

```
configs <- odbcListConfig()

file.edit(configs[1])
```

odbcListDataSources   *List Configured Data Source Names*

Description

Collect information about the available data source names (DSNs). A DSN must be both installed and configured with the driver manager to be included in this list. Configuring a DSN just sets up a lookup table (e.g. in odbc.ini) to allow users to pass only the DSN to dbConnect().

DSNs that are not configured with the driver manager can still be connected to with dbConnect() by providing DSN metadata directly.

Usage

```
odbcListDataSources()
```

Value

A data frame with two columns:

name Name of the data source. The entries in this column can be passed to the dsn argument of dbConnect().

description Data source description.

Configuration

This function interfaces with the driver manager to collect information about the available data source names.

For **MacOS and Linux**, the odbc package supports the unixODBC driver manager. unixODBC looks to the odbc.ini *configuration file* for information on DSNs. Find the location(s) of your odbc.ini file(s) with odbcinst -j.

In this example odbc.ini file:

```
[MySQL]
Driver = MySQL Driver
Database = test
Server = 127.0.0.1
User = root
password = root
Port = 3306
```

...the data source name is MySQL, which will appear in the name column of this function's output. To pass the DSN as the dsn argument to dbConnect(), pass it as a string, like "MySQL". Driver = MySQL Driver references the driver name in odbcListDrivers() output.

Windows is bundled with an ODBC driver manager.

When a DSN is configured with a driver manager, information on the DSN will be automatically passed on to dbConnect() when its dsn argument is set.

For example, with the MySQL data source name configured, and the driver name MySQL Driver appearing in odbcListDrivers() output, the code:

```
con <-
  dbConnect(
    odbc::odbc(),
    Driver = "MySQL Driver",
    Database = "test",
    Server = "127.0.0.1",
    User = "root",
    password = "root",
    Port = 3306
  )
```

...can be written:

```
con <- dbConnect(odbc::odbc(), dsn = "MySQL")
```

In this case, dbConnect() will look up the information defined for MySQL in the driver manager (in our example, odbc.ini) and automatically pass the needed arguments.

See Also

odbcListDrivers()

---

odbcListDrivers   *List Configured ODBC Drivers*

Description

Collect information about the configured driver names. A driver must be both installed and configured with the driver manager to be included in this list. Configuring a driver name just sets up a lookup table (e.g. in odbcinst.ini) to allow users to pass only the driver name to dbConnect().

Driver names that are not configured with the driver manager (and thus do not appear in this function's output) can still be used in dbConnect() by providing a path to a driver directly.

Usage

```
odbcListDrivers(
  keep = getOption("odbc.drivers_keep"),
  filter = getOption("odbc.drivers_filter")
)
```

Arguments

keep, filter   A character vector of driver names to keep in or remove from the results, respec-
                  tively. If NULL, all driver names will be kept, or none will be removed, respec-
                  tively. The odbc.drivers_keep and odbc.drivers_filter options control
                  the argument defaults.

                  Driver names are first processed with keep, then filter. Thus, if a driver name
                  is in both keep and filter, it won't appear in output.

Value

A data frame with three columns.

name Name of the driver. The entries in this column can be passed to the driver argument of
       [dbConnect()](#) (as long as the driver accepts the argument).

attribute Driver attribute name.

value Driver attribute value.

If a driver has multiple attributes, there will be one row per attribute, each with the same driver
name. If a given driver name does not have any attributes, the function will return one row with the
driver name, but the last two columns will be NA.

Configuration

This function interfaces with the driver manager to collect information about the available driver
names.

For **MacOS and Linux**, the odbc package supports the unixODBC driver manager. unixODBC
looks to the odbcinst.ini *configuration file* for information on driver names. Find the location(s)
of your odbcinst.ini file(s) with odbcinst -j.

In this example odbcinst.ini file:

```
[MySQL Driver]
Driver=/opt/homebrew/Cellar/mysql/8.2.0_1/lib/libmysqlclient.dylib
```

Then the driver name is MySQL Driver, which will appear in the name column of this function's
output. To pass the driver name as the driver argument to [dbConnect()](#), pass it as a string, like
"MySQL Driver".

Windows is bundled with an ODBC driver manager.

In this example, function output would include 1 row: the name column would read "MySQL Driver",
attribute would be "Driver", and value would give the file path to the driver. Additional key-
value pairs under the driver name would add additional rows with the same name entry.

When a driver is configured with a driver manager, information on the driver will be automatically
passed on to [dbConnect()](#) when its driver argument is set. For an example, see the same section
in the [odbcListDataSources()](#) help-file. Instead of configuring driver information with a driver
manager, it is also possible to provide a path to a driver directly to [dbConnect()](#).

See Also

odbcListDataSources()

Examples

```
odbcListDrivers()
```

---

odbcListObjects   *List objects in a connection.*

Description

Lists all of the objects in the connection, or all the objects which have specific attributes.

Usage

```
odbcListObjects(connection, ...)
```

Arguments

connection	A connection object, as returned by dbConnect().
...	Attributes to filter by.

Details

When used without parameters, this function returns all of the objects known by the connection. Any parameters passed will filter the list to only objects which have the given attributes; for instance, passing schema = "foo" will return only objects matching the schema foo.

Value

A data frame with name and type columns, listing the objects.

odbcListObjectTypes   *Return the object hierarchy supported by a connection.*

Description

Lists the object types and metadata known by the connection, and how those object types relate to each other.

Usage

```
odbcListObjectTypes(connection)
```

Arguments

connection   A connection object, as returned by dbConnect().

Details

The returned hierarchy takes the form of a nested list, in which each object type supported by the connection is a named list with the following attributes:

contains A list of other object types contained by the object, or "data" if the object contains data

icon An optional path to an icon representing the type

For instance, a connection in which the top-level object is a schema that contains tables and views, the function will return a list like the following:

```
list(schema = list(contains = list(
                    list(name = "table", contains = "data")
                    list(name = "view", contains = "data"))))
```

Value

The hierarchy of object types supported by the connection.

---

odbcPreviewObject   *Preview the data in an object.*

Description

Return the data inside an object as a data frame.

Usage

```
odbcPreviewObject(connection, rowLimit, ...)
```

Arguments

connection	A connection object, as returned by dbConnect().
rowLimit	The maximum number of rows to display.
...	Parameters specifying the object.

Details

The object to previewed must be specified as one of the arguments (e.g. `table = "employees"`); depending on the driver and underlying data store, additional specification arguments may be required.

Value

A data frame containing the data in the object.

---

odbcSetTransactionIsolationLevel
    Set the Transaction Isolation Level for a Connection

Description

Set the Transaction Isolation Level for a Connection

Usage

```
odbcSetTransactionIsolationLevel(conn, levels)
```

Arguments

conn	A [DBIConnection](#) object, as returned by [dbConnect()](#).
levels	One or more of 'read_uncommitted', 'read_committed', 'repeatable_read', 'serializable'.

See Also

https://docs.microsoft.com/en-us/sql/odbc/reference/develop-app/setting-the-transaction-isolation-l

Examples

```
## Not run:
# Can use spaces or underscores in between words.
odbcSetTransactionIsolationLevel(con, "read uncommitted")

# Can also use the full constant name.
odbcSetTransactionIsolationLevel(con, "SQL_TXN_READ_UNCOMMITTED")

## End(Not run)
```

---

quote_value   *Quote special character when connecting*

Description

When connecting to a database using odbc, all the arguments are concatenated into a single connec-
tion string that looks like name1=value1;name2=value2. That means if your value contains = or ;
then it needs to be quoted. Other rules mean that you need to quote any values that starts or ends
with white space, or contains { or }.

This function quotes a string in a way that should work for most drivers, but unfortunately there
doesn't seem to be an approach that works everywhere. If this function doesn't work for you, you'll
need to carefully read the docs for your driver.

Usage

```
quote_value(x)
```

Arguments

x   A string to quote.

Value

A quoted string, wrapped in I().

Examples

```
quote_value("abc")
quote_value("ab'c")

# Real usage is more likely to look like:
## Not run:
library(DBI)
```

```
con <- dbConnect(
  odbc::odbc(),
  dsn = "reallycooldatabase"
  password = odbc::quote_value(Sys.getenv("MY_PASSWORD"))
)

## End(Not run)
```

---

snowflake   *Helper for connecting to Snowflake via ODBC*

Description

Connect to a Snowflake account via the Snowflake ODBC driver.

In particular, the custom dbConnect() method for the Snowflake ODBC driver detects ambient OAuth credentials on platforms like Snowpark Container Services or Posit Workbench.

Usage

```
snowflake()

## S4 method for signature 'Snowflake'
dbConnect(
  drv,
  account = Sys.getenv("SNOWFLAKE_ACCOUNT"),
  driver = NULL,
  warehouse = NULL,
  database = NULL,
  schema = NULL,
  uid = NULL,
  pwd = NULL,
  ...
)
```

Arguments

drv	an object that inherits from DBIDriver, or an existing DBIConnection object (in order to clone an existing connection).
account	A Snowflake account identifier, e.g. "testorg-test_account".
driver	The name of the Snowflake ODBC driver, or NULL to use the default name.
warehouse	The name of a Snowflake compute warehouse, or NULL to use the default.
database	The name of a Snowflake database, or NULL to use the default.
schema	The name of a Snowflake database schema, or NULL to use the default.
uid, pwd	Manually specify a username and password for authentication. Specifying these options will disable ambient credential discovery.
...	Further arguments passed on to dbConnect().

Value

An `OdbcConnection` object with an active connection to a Snowflake account.

Examples

```
## Not run:
# Use ambient credentials.
DBI::dbConnect(odbc::snowflake())

# Use browser-based SSO (if configured). Only works on desktop.
DBI::dbConnect(
  odbc::snowflake(),
  account = "testorg-test_account",
  authenticator = "externalbrowser"
)

# Use a traditional username & password.
DBI::dbConnect(
  odbc::snowflake(),
  account = "testorg-test_account",
  uid = "me",
  pwd = rstudioapi::askForPassword()
)

## End(Not run)
```
