# Testing the Ratio of Two Poisson Rates

Michael P. Fay September 17, 2024

## 1 Example

Here is a quick example of the function rateratio.test. Suppose you have two rates that you assume are Poisson and you want to test that they are different. Suppose you observe 2 events with time at risk of n = 17877 in one group and 9 events with time at risk of m = 16660 in another group. Here is the test:

```
> rateratio.test(c(2,9),c(n,m))
```

Exact Rate Ratio Test, assuming Poisson counts

The result is barely non-significant at the 0.05 level. This example was chosen to make a point, that is why the p-value is so close to 0.05. See Section 5 below.

## 2 Assumptions and Notation

Assume that  $Y \sim Poisson(n\lambda_y)$  and  $X \sim Poisson(m\lambda_x)$ . We are interested in the rate ratio,  $\theta = \lambda_y/\lambda_x$ . The parameters n and m are assumed known and represent the time spent in the Poisson process with the given rates. For example, n could the number of person-years at risk associated with Y. We wish to test one of the three following hypotheses:

less

 $H_0: \quad \theta \ge \Delta$  $H_1: \quad \theta < \Delta$ 

greater

 $H_0: \quad \theta \le \Delta$  $H_1: \quad \theta > \Delta$ 

#### two-sided

$$H_0: \quad \theta = \Delta$$
  
 $H_1: \quad \theta \neq \Delta$ 

For the tests using the rate ratios, we can use the uniformly most powerful (UMP) unbiased test. This test is based on conditioning on the sum X + Y (see e.g., Lehmann and Romano, 2005, p. 125 or p. 152 of Lehmann, 1986). We modify Lehmann's presentation by allowing the constants m and n, representing the time in the Poisson process. We have that

$$Y|X + Y = t \sim Binomial(t, p(\theta))$$

where

$$p(\theta) = \frac{n\lambda_y}{n\lambda_y + m\lambda_x} = \frac{n\theta}{n\theta + m}.$$
 (1)

## 3 Confidence Intervals

Since  $p(\theta)$  is a monotonic increasing function of  $\theta$ , if we have exact confidence intervals for  $p(\theta)$ , then we can transform them to exact confidence intervals for  $\theta$ . The R function binom.test gives exact intervals for binomial observations (see Clopper and Pearson, 1934 or Leemis and Trivedi, 1996). We write the  $100(1-\alpha)\%$  one-sided lower confidence limit for p as  $L_p(Y;\alpha)$  and the  $100(1-\alpha)\%$  one-sided upper confidence limit for p as  $U_p(Y;\alpha)$ . For the  $100(1-\alpha)\%$  two-sided cofidence interval, binom.test and Clopper and Pearson (1934) use the central confidence interval defined as  $[L_p(Y;\alpha/2), L_p(Y;\alpha/2)]$ . The central confidence interval guarantees that

$$Pr[p < L_p(Y; \alpha/2)|p, t] \leq \alpha/2 \text{ for all } p \text{ and } t$$

and

$$Pr[p > U_p(Y; \alpha/2)|p, t] \le \alpha/2$$
 for all  $p$  and  $t$ 

For shorter exact intervals which are not central see Blaker (2000) and the references therein. To obtain confidence intervals for  $\theta$  we set

$$L_p(Y;\alpha) = \frac{nL_{\theta}(Y;\alpha)}{nL_{\theta}(Y;\alpha) + m},$$

and perform some algebra to get

$$L_{\theta}(Y;\alpha) = \frac{mL_p(Y;\alpha)}{n\{1 - L_p(Y;\alpha)\}}.$$

Similarly,

$$U_{\theta}(Y;\alpha) = \frac{mU_{p}(Y;\alpha)}{n\{1 - U_{p}(Y;\alpha)\}}.$$

## 4 P-values

Just as in the last section, we can use results from the tests of p and translate them to tests of  $\theta$ . Thus, for example the one-sided p-value of the test with the alternative hypothesis that  $\theta > \Delta$  is equivalent to the one-sided p-value of the test that  $p > p(\Delta)$ . For the two-sided p-value we use the minimum of 1 or twice the minimum of the two one-sided p-values. There are other ways to define the two-sided p-value but they do not give equivalent inferences with the confidence intervals described above (see Section 5 below).

## 5 Relationship to Other Tests

In the R function binom.test (as least up until R version 4.4.1 (2024-06-14)) the two-sided p-value is calculated by defining more extreme responses as those values with binomial density functions less than or equal to the observed density. This is a valid and reasonable way of defining two-sided p-values but it does not match with the two-sided confidence intervals. Returning to our example from Section 1 but using binom.test we can match the confidence intervals by using equation 1.

```
> n<-17877
> m<-16674
> rateratio.test(c(2,9),c(n,m))$conf.int
[1] 0.02179236 1.00138990
attr(, "conf.level")
[1] 0.95
> b.ci <-binom.test(2,2+9,p=n/(n+m))$conf.int
> theta.ci<-m*b.ci/(n*(1-b.ci))
> theta.ci
[1] 0.02179236 1.00138990
attr(, "conf.level")
[1] 0.95
However, the p-values do not match for a two-sided test of p(1) = n/(n+m).
> R. Version()$version.string
[1] "R version 4.4.1 (2024-06-14)"
> rateratio.test(c(2,9),c(n,m))
        Exact Rate Ratio Test, assuming Poisson counts
data: c(2, 9) with time of c(n, m), null rate ratio 1
p-value = 0.05027
```

```
alternative hypothesis: true rate ratio is not equal to 1
95 percent confidence interval:
0.02179236 1.00138990
sample estimates:
 Rate Ratio
                   Rate 1
                                Rate 2
0.2072681844 0.0001118756 0.0005397625
> binom.test(2,2+9,p=n/(n+m))
        Exact binomial test
data: 2 and 2 + 9
number of successes = 2, number of trials = 11, p-value = 0.03315
alternative hypothesis: true probability of success is not equal to 0.517409
95 percent confidence interval:
0.0228312 0.5177559
sample estimates:
probability of success
             0.1818182
```

The p-values for rateratio.test are internally consistent, i.e., if the two-sided p-value is less than  $\alpha$  then the  $100(1-\alpha/2)\%$  confidence interval does not contain  $\Delta$ . In contrast the p-values for binom.test are not internally consistent as shown by the example. A similar internal inconsistency happens with fisher.test.

```
Fisher's Exact Test for Count Data

data: matrix(c(2, 9, n - 2, m - 9), 2, 2)
p-value = 0.03312
alternative hypothesis: true odds ratio is not equal to 1
95 percent confidence interval:
0.02178155 1.00121047
sample estimates:
odds ratio
0.2072015
```

> fisher.test(matrix(c(2,9,n-2,m-9),2,2))
